The mass spectrum is a fingerprint for each compound because no two molecules are fragmented and ionized in exactly the same manner on electron-impact ionization. In reporting mass spectra the data are normalized by assigning the most intense peak (denoted as base peak) a value of 100. Other peaks are reported as percentages of the base peak.

A very good general survey for interpreting mass spectral data is given by R. M. Silverstein, G. C. Bassler, and T. C. Morrill, *Spectrometric Identification of Organic Compounds*, 4th ed., Wiley, New York, 1981.

#### 7.8.2.1 Initial Steps in Elucidation of a Mass Spectrum

1. Tabulate the prominent ion peaks, starting with the highest mass.
2. Usually only one bond is cleaved. In succeeding fragmentations a new bond is formed for each additional bond that is broken.
3. When fragmentation is accompanied by the formation of a new bond as well as by the breaking of an existing bond, a rearrangement process is involved. These will be even mass peaks when only C, H, and O are involved. The migrating atom is almost exclusively hydrogen; six-membered cyclic transition states are most important.
4. Tabulate the probable groups that (a) give rise to the prominent charged ion peaks and (b) list the neutral fragments.

#### 7.8.2.2 General Rules for Fragmentation Patterns

1. Bond cleavage is more probable at branched carbon atoms: tertiary > secondary > primary. The positive charge tends to remain with the branched carbon.
2. Double bonds favor cleavage beta to the carbon (but see rule 6).
3. A strong parent peak often indicates a ring.
4. Saturated ring systems lose side chains at the alpha carbon. Upon fragmentation, two ring atoms are usually lost.
5. A heteroatom induces cleavage at the bond beta to it.
6. Compounds that contain a carbonyl group tend to break at this group; the positive charge remains with the carbonyl portion.
7. For linear alkanes, the initial fragment lost is an ethyl group (never a methyl group), followed by propyl, butyl, and so on. An intense peak at mass 43 suggests a chain longer than butane.
8. The presence of Cl, Br, S, and Si can be deduced from the unusual isotopic abundance patterns of these elements. These elements can be traced through the positively charged fragments until the pattern disappears or changes due to the loss of one of these atoms to a neutral fragment.
9. When unusual mass differences occur between some fragments ions, the presence of F (mass difference 19), I (mass difference 127), or P (mass difference 31) should be suspected.

#### 7.8.2.3 Characteristic Low-Mass Fragment Ions

Mass 30 = Primary amines

Masses 31, 45, 59 = Alcohol or ether

Masses 19 and 31 = Alcohol

Mass 66 = Monobasic carboxylic acid

Masses 77 and 91 = Benzene ring

#### 7.8.2.4 Characteristic Low-Mass Neutral Fragments from the Molecular Ion

Mass 18 ( $\text{H}_2\text{O}$ ) = From alcohols, aldehydes, ketones

Mass 19 (F) and 20 (HF) = Fluorides

Mass 27 (HCN) = Aromatic nitriles or nitrogen heterocycles

Mass 29 = Indicates either CHO or  $\text{C}_2\text{H}_5$

Mass 30 = Indicates either  $\text{CH}_2\text{O}$  or NO

Mass 33 (HS) and 34 ( $\text{H}_2\text{S}$ ) = Thiols

Mass 42 =  $\text{CH}_2\text{CO}$  via rearrangement from a methyl ketone or an aromatic acetate or an aryl- $\text{NHCOCH}_3$  group

Mass 43 =  $\text{C}_3\text{H}_7$  or  $\text{CH}_3\text{CO}$

Mass 45 =  $\text{COOH}$  or  $\text{OC}_2\text{H}_5$

Table 7.76 is condensed, with permission, from the Catalog of Mass Spectral Data of the American Petroleum Institute Research Project 44. These, and other tables, should be consulted for further and more detailed information.

Included in the table are all compounds for which information was available through the  $\text{C}_7$  compounds. The mass number for the five most important peaks for each compound are listed, followed in each case by the relative intensity in parentheses. The intensities in all cases are normalized to the *n*-butane 43 peak taken as 100. Another method for expressing relative intensities is to assign the base peak a value of 100 and express the relative intensities of the other peaks as a ratio to the base peak. Taking ethyl nitrate as an example, the tabulated values would be

|               |             |         |          |          |          |
|---------------|-------------|---------|----------|----------|----------|
| Ethyl nitrate | 91(0.01)(P) | 46(100) | 29(44.2) | 30(30.5) | 76(24.2) |
|---------------|-------------|---------|----------|----------|----------|

The compounds are arranged in the table according to their molecular formulas. Each formula is arranged alphabetically, except that C is first if carbon occurs in the molecules, followed by H if it occurs. The formulas are then arranged alphabetically and according to increasing number of atoms of each kind, all  $\text{C}_4$  compounds being listed before any  $\text{C}_5$  compounds, and so on.

Nearly all these spectra have been recorded using 70-V electrons to bombard the sample molecules.

TABLE 7.76 Condensed Table of Mass Spectra

| Molecular<br>formula                          | Name                              | Mass numbers (and intensities) of: |              |                               |          |          |
|-----------------------------------------------|-----------------------------------|------------------------------------|--------------|-------------------------------|----------|----------|

8.1 ACTIVITY COEFFICIENTS

Although it is not possible to measure an individual ionic activity coefficient,  $f_i$ , it may be estimated from the following equation of the Debye-Hückel theory:

$$-\log f_i = \frac{Az_i^2\sqrt{I}}{1 + B\hat{a}\sqrt{I}}$$

where  $I$  is the ionic strength of the medium, and  $\hat{a}$  is the ion-size parameter—the effective ionic radius (Table 8.2). The values of  $A$  and  $B$  vary with the temperature and dielectric constant of the solvent; values from 0 to 100°C for aqueous medium ( $\hat{a}$  in angstrom units) are listed in Table 8.3. Corresponding values of  $A$  and  $B$  for unit weight of solvent (when employing molality) can be obtained by multiplying the corresponding values for unit volume (molarity units) by the square root of the density of water at the appropriate temperature.

The ionic strength can be estimated from the summation of the product molarity times ionic charge squared for all the ionic species present in the solution, i.e.,  $I = 0.5(c_1z_1^2 + c_2z_2^2 + \cdots + c_iz_i^2)$ .

Values for the activity coefficients of ions in water at 25°C are given in Table 8.1 in terms of their effective ionic radii.

At moderate ionic strengths a considerable improvement is effected by subtracting a term  $bI$  from the Debye-Hückel expression;  $b$  is an adjustable parameter which is 0.2 for water at 25°C. Table 8.4 gives the values of the ionic activity coefficients (for  $z_i$  from 1 to 6) with  $\hat{a}$  taken to be 4.6Å.

In general, the mean ionic activity coefficient is given by

$$f_{\pm} = {}^{(x+y)}\sqrt{f_+^x f_-^y}$$

**TABLE 8.1** Individual Activity Coefficients of Ions in Water at 25°C

The values for unit weight of solvent (molality scale) can be obtained by multiplying the corresponding values for unit volume by the square root of the density of water at the appropriate temperature.

**TABLE 8.4** Individual Ionic Activity Coefficients at Higher Ionic Strengths at 25°C

The values were calculated from the modified Debye-Hückel equation utilizing the modifications proposed by Robinson and by Guggenheim and Bates:

$$-\frac{\log f_i}{z_i^2} = \frac{0.511I}{1 + 1.5I} - 0.2I$$

where  $I$  is the ionic strength and  $\hat{a}$  is assumed to be 4.6 Å.

| $I$  | $-\frac{\log_{10} f_i}{z_i^2}$ | $f_i$ for $z_i =$ |       |                    |        |                     |          |

8.2 EQUILIBRIUM CONSTANTS

TABLE 8.5 Ionic Product Constant of Water

This table gives values of pKw on a molal scale, where Kw is the ionic activity product constant of water. Values are from W. L. Marshall and E. U. Franck, *J. Phys. Chem. Ref. Data*, **10**:295 (1981).

| Temp.,<br>°C | pKw    | Temp.,<br>°C | pKw    | Temp.,<br>°C | pKw    |
|--------------|--------|--------------|--------|--------------|--------|
| 0            | 14.938 | 45           | 13.405 | 95           | 12.345 |
| 5            | 14.727 | 50           | 13.275 | 100          | 12.264 |
| 10           | 14.528 | 55           | 13.152 | 125          | 11.911 |
| 15           | 14.340 | 60           | 13.034 | 150          | 11.637 |
| 18           | 14.233 | 65           | 12.921 | 175          | 11.431 |
| 20           | 14.163 | 70           | 12.814 | 200          | 11.288 |
| 25           | 13.995 | 75           | 12.711 | 225          | 11.207 |
| 30           | 13.836 | 80           | 12.613 | 250          | 11.192 |
| 35           | 13.685 | 85           | 12.520 | 275          | 11.251 |
| 40           | 13.542 | 90           | 12.431 | 300          | 11.406 |

TABLE 8.6 Solubility Product Constants

The data refer to various temperatures between 18 and 25°C, and were compiled from values cited by Bjerrum, Schwarzenbach, and Sillen, *Stability Constants of Metal Complexes*, part II, Chemical Society, London, 1958, and values taken from publications of the IUPAC Solubility Data Project: *Solubility Data Series*, International Union of Pure and Applied Chemistry, Pergamon Press, Oxford, 1979–1992; H. L. Clever, and F. J. Johnston, *J. Phys. Chem. Ref. Data*, **9**:751 (1980); Y. Marcus, *Ibid.* **9**:1307 (1980); H. L. Clever, S. A. Johnson, and M. E. Derrick, *Ibid.* **14**:631 (1985), and **21**:941 (1992).

In the table, “L” is the abbreviation of the organic ligand.

| Compound                     | Formula                                          | pK <sub>sp</sub> | K <sub>sp</sub>          |
|------------------------------|--------------------------------------------------|------------------|--------------------------|
| Actinium<br>hydroxide        | Ac(OH) <sub>3</sub>                              | 15               | 1 × 10 <sup>−15</sup>    |
| Aluminum<br>arsonate         | AlAsO <sub>4</sub>                               | 15.80            | 1.6 × 10 <sup>−16</sup>  |
| cupferrate                   | AlL <sub>3</sub>                                 | 18.64            | 2.3 × 10 <sup>−19</sup>  |
| hydroxide                    | Al(OH) <sub>3</sub>                              | 32.89            | 1.3 × 10 <sup>−33</sup>  |
| phosphate                    | AlPO <sub>4</sub>                                | 20.01            | 9.84 × 10 <sup>−21</sup> |
| 8-quinolinolate              | AlL <sub>3</sub>                                 | 29.00            | 1.00 × 10 <sup>−29</sup> |
| selenide                     | Al <sub>2</sub> Se <sub>3</sub>                  | 24.4             | 4 × 10 <sup>−25</sup>    |
| sulfide                      | Al <sub>2</sub> S <sub>3</sub>                   | 6.7              | 2 × 10 <sup>−7</sup>     |
| Americium<br>(III) hydroxide | Am(OH) <sub>3</sub>                              | 19.57            | 2.7 × 10 <sup>−20</sup>  |
| (IV) hydroxide               | Am(OH) <sub>4</sub>                              | 56               | 1 × 10 <sup>−56</sup>    |
| Ammonium<br>uranyl arsenate  | NH <sub>4</sub> UO <sub>2</sub> AsO <sub>4</sub> | 23.77            | 1.7 × 10 <sup>−24</sup>  |
| Arsenic<br>(III) sulfide     | As <sub>2</sub> S <sub>3</sub>                   | 21.68            | 2.1 × 10 <sup>−22</sup>  |

### 8.2.1 Proton-Transfer Reactions

The  $pK_a$  values listed in Tables 8.7 and 8.8 are the negative (decadic) logarithms of the acidic dissociation constant, i.e.,  $-\log_{10} K_a = pK_a$ . For the general proton-transfer reaction

the acidic dissociation constant is formulated as follows:

$$K_a = \frac{[H^+][B]}{[HB]}$$

The most common charge types for the acid HB and its conjugate base B are

Acids which have more than one acidic hydrogen ionize in steps, as shown for phosphoric acid:

If the basic dissociation constant  $K_b$  for the equilibrium such as

is required,  $pK_b$  may be calculated from the relationship

$$pK_b = pK_w - pK_a$$

If a desired organic acid is not entered in Table 8.8, a useful estimate of its  $pK_a$  value can sometimes be obtained by making a comparison with recognizably similar compounds for which  $pK_a$  values are known: (1) alkyl chains, alicyclic rings, or saturated carbocyclic rings fused to aromatic or heterocyclic rings can be replaced by methyl or ethyl groups; (2) acid-strengthening inductive and mesomeric effects of a nitro group attached to an aromatic ring are very similar to those of a nitrogen atom located at the same position in a heteroaromatic ring (e.g., 3-hydroxypyridine and 3-nitrophenol).

Hammett and Taft substituent constants and, in particular, Tables 9.1 through 9.4 may also prove useful for estimating  $pK_a$  values.

### 8.2.1.1 Calculation of the Approximate pH Value of Solutions

*Strong acid:*  $\text{pH} = -\log [\text{acid}]$

*Strong base:*  $\text{pH} = 14.00 + \log [\text{base}]$

*Weak acid:*  $\text{pH} = \frac{1}{2}pK_a - \frac{1}{2} \log [\text{acid}]$

*Weak base:*  $\text{pH} = 14.00 - \frac{1}{2}pK_b + \frac{1}{2} \log [\text{base}]$

*Salt formed by a weak acid and a strong base:*

$$\text{pH} = 7.00 + \frac{1}{2}pK_a + \frac{1}{2} \log [\text{salt}]$$

*Acid salts of a dibasic acid:*

$$\text{pH} = \frac{1}{2}pK_1 + \frac{1}{2}pK_2 - \frac{1}{2} \log [\text{salt}] + \frac{1}{2} \log (K_1 + [\text{salt}])$$

*Buffer solution consisting of a mixture of a weak acid and its salt:*

$$\text{pH} = pK_a + \log \left( \frac{[\text{salt}] + [\text{H}_3\text{O}^+] - [\text{OH}^-]}{[\text{acid}] - [\text{H}_3\text{O}^+] + [\text{OH}^-]} \right)$$

### 8.2.1.2 Calculation of Concentrations of Species Present at a Given pH

$$\begin{aligned}\alpha_0 &= \frac{[\text{H}^+]^n}{[\text{H}^+]^n + K_1[\text{H}^{+}]^{n-1} + K_1K_2[\text{H}^{+}]^{n-2} + \cdots + K_1K_2 \cdots K_n} = \frac{[\text{H}_n\text{A}]}{C_{\text{acid}}} \\ \alpha_1 &= \frac{K_1[\text{H}^+]^{n-1}}{[\text{H}^+]^n + K_1[\text{H}^{+}]^{n-1} + K_1K_2[\text{H}^{+}]^{n-2} + \cdots + K_1K_2 \cdots K_n} = \frac{[\text{H}_{n-1}\text{A}^-]}{C_{\text{acid}}} \\ \alpha_2 &= \frac{K_1K_2[\text{H}^+]^{n-2}}{[\text{H}^+]^n + K_1[\text{H}^{+}]^{n-1} + K_1K_2[\text{H}^{+}]^{n-2} + \cdots + K_1K_2 \cdots K_n} = \frac{[\text{H}_{n-2}\text{A}^{2-}]}{C_{\text{acid}}} \\ &\vdots \\ \alpha_n &= \frac{K_1K_2 \cdots K_n}{[\text{H}^+]^n + K_1[\text{H}^{+}]^{n-1} + K_1K_2[\text{H}^{+}]^{n-2} + \cdots + K_1K_2 \cdots K_n} = \frac{[\text{A}^{n-}]}{C_{\text{acid}}}\end{aligned}$$

**TABLE 8.8**  $pK_a$  Values of Organic Materials in Water at 25°C

Ionic strength  $\mu$  is zero unless otherwise indicated. Protonated cations are designated by (+1), (+ 2), etc., after the  $pK_a$  value; neutral species by (0), if not obvious; and negatively charged acids by (−1), (−2), etc.

| Substance                                                  | $pK_1$     | $pK_2$                   | $pK_3$ | $pK_4$ |

**TABLE 8.9** Selected Equilibrium Constants in Aqueous Solution at Various Temperatures

**Abbreviations Used in the Table**

- (+ 1), protonated cation
- (0), neutral molecule
- (− 1), singly ionized anion
- (− 2), doubly ionized anion
- $pK_{\text{auto}}$ , negative logarithm (base 10) of autoprotolysis constant
- $pK_{\text{sp}}$ , negative logarithm (base 10) of solubility product

8.2.2 Formation Constants of Metal Complexes

Each value listed in Tables 8.12 and 8.13 is the logarithm of the overall formation constant for the cumulative binding of a ligand  $L$  to the central metal cation  $M$ , viz.:

|                 | Cumulative<br>formation constant | Stepwise<br>stability constants |
|-----------------|----------------------------------|---------------------------------|
| $M + L = ML$    | $K_1$                            | $k_1$                           |
| $M + 2L = ML_2$ | $K_2$                            | $k_1 k_2$                       |
| .....           |                                  |                                 |
| $M + nL = ML_n$ | $K_n$                            | $k_1 k_2 \cdots k_n$            |

As an example, the entries in Table 8.12 for the zinc ammine complexes represent these equilibria:

If the stepwise stability or formation constants of the reactions are desired, for the first step  $\log K_1 = \log k_1 = 2.37$ . For the second and succeeding steps the equilibria and corresponding constants are as follows:

The reverse of the association or formation reactions would represent the dissociation or instability constant for the systems, i.e.,  $-\log K_f = \log K_{\text{instab}}$ .

The data in the tables generally refer to temperatures of about 20 to 25°C. Most of the values in Table 8.12 refer to zero ionic strength, but those in Table 8.13 often refer to a finite ionic strength.

**TABLE 8.12** Cumulative Formation Constants for Metal Complexes with Inorganic Ligands

|                 | $\log K_1$              | $\log K_2$ | $\log K_3$ | $\log K_4$ | $\log K_5$ | $\log K_6$ |
|-----------------|-------------------------|------------|------------|------------|------------|------------|

8.3 BUFFER SOLUTIONS

8.3.1 Standard Reference pH Buffer Solutions

The assigned values of  $pH_s$ , according to the Bates-Guggenheim convention [*Pure Applied Chem.* 1:163 (1960)], for the primary standard solutions prepared from salts issued by the National Institute for Science and Technology (NIST, US) (U.S.) are given in Table 8.14. These are smoothed values. The ionic strength of these reference solutions is 0.1 or less. Strictly speaking the NIST scale uses a molality concentration system; however, values are given in molarity units for convenience.

As a result of a variable liquid-junction potential, the measured pH may be expected to differ seriously from the  $pa_H$  determined from cells without a liquid junction in solutions of high acidity or high alkalinity. Merely to affirm the proper functioning of the glass electrode at the extreme ends of the pH scale, two secondary standards are included in Table 8.14. In addition, values for a 0.1 *m* solution of HCl are given to extend the pH scale up to 275°C [see R. S. Greeley, *Anal. Chem.* 32:1717 (1960)]:

|                |      |      |      |      |      |      |      |         |
|----------------|------|------|------|------|------|------|------|---------|
| $t, ^\circ C:$ | 25   | 60   | 90   | 125  | 150  | 175  | 200  | 225–275 |
| pH:            | 1.10 | 1.11 | 1.12 | 1.13 | 1.14 | 1.15 | 1.16 | 1.2     |

Uncertainties in the values are  $\pm 0.03$  pH unit from 25 to 90°C,  $\pm 0.05$  pH unit from 125 to 200°C, and  $\pm 0.1$  pH unit from 225 to 275°C.

| Buffer value β  | 0.027    | 0.034           | 0.016         | 0.029                             | 0.016                             | 0.020                                         | 0.029                           |

For the secondary pH reference standards, the buffer value is 0.070 for potassium tetroxalate and 0.09 for calcium hydroxide.

To prepare the standard pH buffer solutions recommended by the National Bureau of Standards (U.S.), the indicated weights of the pure materials in Table 8.15 should be dissolved in water of specific conductivity not greater than 5 micromhos. The tartrate, phthalate, and phosphates can be dried for 2 h at 100°C before use. Potassium tetroxalate and calcium hydroxide need not be dried. Fresh-looking crystals of borax should be used. Before use, excess solid potassium hydrogen tartrate and calcium hydroxide must be removed. Buffer solutions pH 6 or above should be stored in plastic containers and should be protected from carbon dioxide with soda-lime traps. The solutions should be replaced within 2 to 3 weeks, or sooner if formation of mold is noticed. A crystal of thymol may be added as a preservative.

8.3.2 Standards for pH Measurement of Blood and Biological Media

Blood is a well-buffered medium. In addition to the NBS phosphate standard of 0.025 *M* (pH<sub>s</sub> = 6.480 at 38°C), another reference solution containing the same salts, but in the molal ratio 1 : 4, has an ionic strength of 0.13. It is prepared by dissolving 1.360 g of KH<sub>2</sub>PO<sub>4</sub> and 5.677 g of Na<sub>2</sub>HPO<sub>4</sub> (air weights) in carbon dioxide-free water to make 1 liter of solution. The pH<sub>s</sub> is 7.416 ± 0.004 at 37.5 and 38°C.

The compositions and pH<sub>s</sub> values of *tris*(hydroxymethyl)aminomethane, covering the pH range 7.0 to 8.9, are listed in Table 8.16.

**TABLE 8.16** Composition and pH Values of Buffer Solutions

Values based on the conventional activity pH scale as defined by the National Bureau of Standards (U.S.) and pertain to a temperature of 25°C [Ref: Bower and Bates, *J. Research Natl. Bur. Standards (U.S.)*, **55**:197 (1955) and Bates and Bower, *Anal. Chem.*, **28**:1322 (1956)]. Buffer value is denoted by column headed  $\beta$ .

| 25 ml 0.2M KCl +<br>x ml 0.2M HCl,<br>Diluted to 100 ml                                                                 |      |         | 50 ml 0.1M KH Phthalate<br>+ x ml 0.1M HCl,<br>Diluted to 100 ml                                                                                      |      |         | 50 ml 0.1M KH Phthalate<br>+ x ml 0.1M NaOH,<br>Diluted to 100 ml                                                                           |      |         |

Suc = succinate

Sal = salicylate

8.3.3 Buffer Solutions Other Than Standards

The range of the buffering effect of a single weak acid group is approximately one pH unit on either side of the  $pK_a$ . The ranges of some useful buffer systems are collected in Table 8.19. After all the components have been brought together, the pH of the resulting solution should be determined at the temperature to be employed with reference to standard reference solutions. Buffer components should be compatible with other components in the system under study; this is particularly significant for buffers employed in biological studies. Check tables of formation constants to ascertain whether metal-binding character exists.

TABLE 8.19 pH Values of Biological and Other Buffers for Control Purposes

| Materials                                                                        | Acronym             | $pK_a$      | pH range |
|----------------------------------------------------------------------------------|---------------------|-------------|----------|
| <i>p</i> -Toluenesulfonate and <i>p</i> -toluenesulfonic acid                    |                     | 1.7         | 1.1–3.3  |
| Glycine and HCl                                                                  |                     | 2.35        | 1.0–3.7  |
| Citrate and HCl                                                                  |                     | 3.13        | 1.3–4.7  |
| Formate and HCl                                                                  |                     | 3.71        | 2.8–4.6  |
| Succinate and borax                                                              |                     | 4.21, 5.64  | 3.0–5.8  |

When there are two or more acid groups per molecule, or a mixture is composed of several overlapping acids, the useful range is larger. Universal buffer solutions consist of a mixture of acid groups which overlap such that successive  $pK_a$  values differ by 2 pH units or less. The Prideaux-Ward mixture comprises phosphate, phenyl acetate, and borate plus HCl and covers the range from 2 to 12 pH units. The McIlvaine buffer is a mixture of citric acid and  $\text{Na}_2\text{HPO}_4$  that covers the range from pH 2.2 to 8.0. The Britton-Robinson system consists of acetic acid, phosphoric acid, and boric acid plus NaOH and covers the range from pH 4.0 to 11.5. A mixture composed of  $\text{Na}_2\text{CO}_3$ ,  $\text{NaH}_2\text{PO}_4$ , citric acid, and 2-amino-2-methyl-1,3-propanediol covers the range from pH 2.2 to 11.0.

General directions for the preparation of buffer solutions of varying pH but fixed ionic strength are given by Bates.\* Preparation of McIlvaine buffered solutions at ionic strengths of 0.5 and 1.0 and Britton-Robinson solutions of constant ionic strength have been described by Elving et al.† and Frugoni,‡ respectively.

### 8.4.1 Electrometric Measurement of pH

The pH value is defined for an aqueous solution in an operational (arbitrary but reproducible) manner according to the Bates-Guggenheim convention:

$$\text{pH}_x = \text{pH}_s + \frac{E_x - E_s}{2.3026RT/F}$$

where  $R$  is the gas constant per mole,  $T$  is the temperature on the absolute scale, and  $F$  is the faraday. The  $\text{pH}_x$  of the unknown medium is calculated from that of an accepted standard ( $\text{pH}_s$ ) and the measured difference in the emf ( $E$ ) of the electrode combination when the standard solution is removed from the cell and replaced by the unknown. The double vertical line marks a liquid junction. Electrodes as fabricated exhibit variations in the reproducibility of the reference electrode, in the liquid-junction potential, and, with glass electrodes, in the asymmetry potential. These differences are all eliminated in the standardizing procedure with standard reference pH buffers. (See R. G. Bates, *Determination of pH, Theory and Practice*, Wiley, New York, 1964.)

|                                          |                                                     |                                                    |                        |
|------------------------------------------|-----------------------------------------------------|----------------------------------------------------|------------------------|
| Electrode reversible<br>to hydrogen ions | Standard reference<br>buffer or unknown<br>solution | Salt bridge<br>(KCl. 3.5 <i>M</i><br>or saturated) | Reference<br>electrode |
|------------------------------------------|-----------------------------------------------------|----------------------------------------------------|------------------------|

An electrometric pH-measurement system consists of (1) pH-responsive electrode, (2) reference electrode, and (3) potential-measuring device—some form of high-impedance electronic voltmeter for glass-electrode combinations and this or a potentiometer arrangement for other pH-responsive electrodes. Electronic pH meters are simply voltmeters with scale divisions in pH units which are equivalent to the values of  $2.3026RT/F$  (in mV) per pH unit. Values of this function at several temperatures are given in Table 8.22. There is no compensation incorporated in the meter for the changes in pH of the test solution as a function of temperature. Reliability of an indicator–reference electrode combination must be ascertained by standardization of the pH meter with one standard buffer and checking the pH response by immersing the combination in a second and different reference buffer.

The temperature compensator on a pH meter varies the instrument definition of a pH unit from 54.20 mV at 0°C to perhaps 66.10 mV at 60°C. This permits one to measure the pH of the sample (and reference buffer standard) at its actual temperature and thus avoid error due to dissociation equilibria and to junction potentials which have significant temperature coefficients.

8.5 INDICATORS

TABLE 8.23 Indicators for Aqueous Acid-Base Titrations

This table lists some selected indicators. The pH range or transition interval given in the third column may vary appreciably from one observer to another, and, in addition, it is affected by ionic strength, temperature, and illumination; consequently only approximate values can be given. They should be considered to refer to solutions having low ionic strengths and a temperature of about 25°C. In the fourth column the  $pK_a$  ( $-\log K_a$ ) of the indicator as determined spectrophotometrically is listed. In the fifth column the wavelength of maximum absorption is given first for the acidic and then for the basic form of the indicator, and the same order is followed in giving the colors in the sixth column. The abbreviations used to describe the colors of the two forms of the indicator are as follows:

B, blue                      G, green  
V, violet                    P, purple  
Y, yellow                  R, red  
O, orange                 O-Br, orange-brown  
C, colorless

| Indicator                     | Chemical name                                     | pH range | $pK_a$ | $\lambda_{\max}$ , nm | Color change |
|-------------------------------|---------------------------------------------------|----------|--------|-----------------------|--------------|

**TABLE 8.24** Mixed Indicators

Mixed indicators give sharp color changes and are especially useful in titrating to a given titration exponent ( $pI$ ).

The information given in this table is from the two-volume work *Volumetric Analysis* by Kolthoff and Stenger, published by Interscience Publishers, Inc., New York, 1942 and 1947, and reproduced with their permission.

| Composition of Indicator Solution                | $pI$ | Color        |             | Notes                                                                        |
|--------------------------------------------------|------|--------------|-------------|------------------------------------------------------------------------------|
|                                                  |      | Acid         | Alkaline    |                                                                              |
| 1 part 0.1% methyl yellow in alc.                | *    | Blue-violet  | Green       | Still green at pH 3.4, blue-violet at 3.2†                                   |
| 1 part 0.1% methylene blue in alc.               | 3.25 |              |             |                                                                              |
| 1 part 0.14% xylene cyanol FF in alc.            | *    |              |             |                                                                              |
| 1 part 0.1% methyl orange in aq.                 | 3.8  | Violet       | Green       | Color is gray at pH 3.8                                                      |
| 1 part 0.1% methyl orange in aq.                 | *    |              |             |                                                                              |
| 1 part 0.25% indigo carmine in aq.               | 4.1  | Violet       | Green       | Good indicator, especially in artificial light                               |
| 1 part 0.1% methyl orange in aq.                 |      |              |             |                                                                              |
| 1 part 0.1% aniline blue in aq.                  | 4.3  | Violet       | Green       |                                                                              |
| 1 part 0.1% bromcresol green sodium salt in aq.  |      | Orange       | Blue-green  | Yellow at pH 3.5, greenish yellow at 4.0, weakly green at 4.3                |
| 1 part 0.02% methyl orange in aq.                | 4.3  |              |             |                                                                              |
| 3 parts 0.1% bromcresol green in alc.            |      | Wine-red     | Green       | Very sharp color change†                                                     |
| 1 part 0.2% methyl red in alc.                   | 5.1  |              |             |                                                                              |
| 1 part 0.2% methyl red in alc.                   | *    | Red-violet   | Green       | Color is red-violet at pH 5.2, a dirty blue at 5.4, and a dirty green at 5.6 |
| 1 part 0.1% methylene blue in alc.               | 5.4  |              |             |                                                                              |
| 1 part 0.1% chlorphenol red sodium salt in aq.   |      |              |             |                                                                              |
| 1 part 0.1% aniline blue in water                | 5.8  | Green        | Violet      | Pale violet at pH 5.8                                                        |
| 1 part 0.1% bromcresol green sodium salt in aq.  |      | Yellow-green | Blue-violet | Blue-green at pH 5.4, blue at 5.8, blue with a touch of violet at 6.0,       |
| 1 part 0.1% chlorphenol red sodium salt in aq.   | 6.1  |              |             | blue-violet at 6.2                                                           |
| 1 part 0.1% bromcresol purple sodium salt in aq. |      | Yellow       | Violet-blue | Yellow-violet at pH 6.2, violet at 6.6, blue-violet at 6.8                   |
| 1 part 0.1% bromthymol blue sodium salt in aq.   | 6.7  |              |             |                                                                              |
| 2 parts 0.1% bromthymol blue sodium salt in aq.  |      | Violet       | Blue        |                                                                              |
| 1 part 0.1% azolitmin in aq.                     | 6.9  |              |             |                                                                              |

|                                                  |   |      |             |           |                                                                    |
|--------------------------------------------------|---|------|-------------|-----------|--------------------------------------------------------------------|
| 1 part 0.1% neutral red in alc.                  | * |      | Violet-blue | Green     | Violet blue at pH 7.0†                                             |
| 1 part 0.1% methylene blue in alc.               |   | 7.0  |             |           |                                                                    |
| 1 part 0.1% neutral red in alc.                  |   |      | Rose        | Green     | Dirty green at pH 7.4, pale rose at 7.2, clear rose at 7.0         |
| 1 part 0.1% bromthymol blue in alc.              |   | 7.2  |             |           |                                                                    |
| 2 parts 0.1% cyanine in 50% alc.                 |   |      | Yellow      | Violet    | Orange at pH 7.2, beautiful violet at 7.4, color fades on standing |
| 1 part 0.1% phenol red in 50% alc.               |   | 7.3  |             |           |                                                                    |
| 1 part 0.1% bromthymol blue sodium salt in aq.   |   |      | Yellow      | Violet    | Dirty green at pH 7.2, pale violet at 7.4, strong violet at 7.6†   |
| 1 part 0.1% phenol red sodium salt in aq.        |   | 7.5  |             |           |                                                                    |
| 1 part 0.1% cresol red sodium salt in aq.        |   |      | Yellow      | Violet    | Rose at pH 8.2, distinctly violet at 8.4†                          |
| 3 parts 0.1% thymol blue sodium salt in aq.      |   | 8.3  |             |           |                                                                    |
| 2 parts 0.1% $\alpha$ -naphtholphthalein in alc. | * |      | Pale rose   | Violet    | Pale violet at pH 8.2, strong violet at 8.4                        |
| 1 part 0.1% cresol red in alc.                   |   | 8.3  |             |           |                                                                    |
| 1 part 0.1% $\alpha$ -naphtholphthalein in alc.  |   |      | Pale rose   | Violet    | Pale green at pH 8.6, violet at 9.0                                |
| 3 parts 0.1% phenolphthalein in alc.             |   | 8.9  |             |           |                                                                    |
| 1 part 0.1% phenolphthalein in alc.              |   |      | Green       | Violet    | Pale blue at pH 8.8, violet at 9.0                                 |
| 2 parts 0.1% methyl green in alc.                |   | 8.9  |             |           |                                                                    |
| 1 part 0.1% thymol blue in 50% alc.              |   |      | Yellow      | Violet    | From yellow thru green to violet†                                  |
| 3 parts 0.1% phenolphthalein in 50% alc.         |   | 9.0  |             |           |                                                                    |
| 1 part 0.1% phenolphthalein in alc.              |   |      | Colorless   | Violet    | Rose at pH 9.6, violet at 10; sharp color change                   |
| 1 part 0.1% thymolphthalein in alc.              |   | 9.9  |             |           |                                                                    |
| 1 part 0.1% phenolphthalein in alc.              |   |      |             |           |                                                                    |
| 2 parts 0.2% Nile blue in alc.                   |   | 10.0 | Blue        | Red       | Violet at pH 10†                                                   |
| 2 parts 0.1% thymolphthalein in alc.             |   |      |             |           |                                                                    |
| 1 part 0.1% alizarin yellow in alc.              |   | 10.2 | Yellow      | Violet    | Sharp color change                                                 |
| 2 parts 0.2% Nile blue in aq.                    |   |      | Green       | Red-brown |                                                                    |
| 1 part 0.1% alizarin yellow in alc.              |   | 10.8 |             |           |                                                                    |

\* Keep in a dark bottle. † Excellent indicator.

TABLE 8.25 Fluorescent Indicators

| Name                                                   | pH Range     | Color Change<br>Acid to Base | Indicator<br>Solution            |
|--------------------------------------------------------|--------------|------------------------------|----------------------------------|
| Benzoflavine                                           | − 0.3 to 1.7 | Yellow to green              | 1                                |
| 3,6-Dihydroxyphthalimide                               | 0 to 2.4     | Blue to green                | 1                                |
|                                                        | 6.0 to 8.0   | Green to yellow/green        |                                  |
| Eosin (tetrabromofluorescein)                          | 0 to 3.0     | Non-fl to green              | 4, 1%                            |
| 4-Ethoxyacridone                                       | 1.2 to 3.2   | Green to blue                | 1                                |
| 3,6-Tetramethyldiaminoxanthone                         | 1.2 to 3.4   | Green to blue                | 1                                |
| Esculin                                                | 1.5 to 2.0   | Weak blue to strong blue     |                                  |
| Anthranilic acid                                       | 1.5 to 3.0   | Non-fl to light blue         | 2 (50% ethanol)                  |
|                                                        | 4.5 to 6.0   | Light blue to dark blue      |                                  |
|                                                        | 12.5 to 14   | Dark blue to non-fl          |                                  |
| 3-Amino-1-naphthoic acid                               | 1.5 to 3.0   | Non-fl to green              | 2 (as sulfate<br>in 50% ethanol) |
|                                                        | 4.0 to 6.0   | Green to blue                |                                  |
|                                                        | 11.6 to 13.0 | Blue to non-fl               |                                  |
| 1-Naphthylamino-6-sulfonamide<br>(also the 1-, 7-)     | 1.9 to 3.9   | Non-fl to green              | 3                                |
|                                                        | 9.6 to 13.0  | Green to non-fl              |                                  |
| 2-Naphthylamino-6-sulfonamide<br>(also the 2-, 8-)     | 1.9 to 3.9   | Non-fl to dark blue          | 3                                |
|                                                        | 9.6 to 13.0  | Dark blue to non-fl          |                                  |
| 1-Naphthylamino-5-sulfonamide                          | 2.0 to 4.0   | Non-fl to yellow/orange      | 3                                |
|                                                        | 9.5 to 13.0  | Yellow/orange to non-fl      |                                  |
| 1-Naphthoic acid                                       | 2.5 to 3.5   | Non-fl to blue               | 4                                |
| Salicylic acid                                         | 2.5 to 4.0   | Non-fl to dark blue          | 4 (0.5%)                         |
| Phloxin BA extra<br>(tetrachlorotetrabromofluorescein) | 2.5 to 4.0   | Non-fl to dark blue          | 2                                |
| Erythrosin B (tetraiodofluorescein)                    | 2.5 to 4.0   | Non-fl to light green        | 4 (0.2%)                         |
| 2-Naphthylamine                                        | 2.8 to 4.4   | Non-fl to violet             | 1                                |
| Magdala red                                            | 3.0 to 4.0   | Non-fl to purple             |                                  |
| <i>p</i> -Aminophenylbenzenesulfonamide                | 3.0 to 4.0   | Non-fl to light blue         | 3                                |
| 2-Hydroxy-3-naphthoic acid                             | 3.0 to 6.8   | Blue to green                | 4 (0.1%)                         |
| Chromotropic acid                                      | 3.1 to 4.4   | Non-fl to light blue         | 4 (5%)                           |
| 1-Naphthionic acid                                     | 3 to 4       | Non-fl to blue               | 4                                |
|                                                        | 10 to 12     | Blue to yellow-green         |                                  |
| 1-Naphthylamine                                        | 3.4 to 4.8   | Non-fl to blue               | 1                                |
| 5-Aminosalicilic acid                                  | 3.1 to 4.4   | Non-fl to light green        | 1 (0.2% fresh)                   |
| Quinine                                                | 3.0 to 5.0   | Blue to weak violet          | 1 (0.1%)                         |
|                                                        | 9.5 to 10.0  | Weak violet to non-fl        |                                  |
| <i>o</i> -Methoxybenzaldehyde                          | 3.1 to 4.4   | Non-fl to green              | 4 (0.2%)                         |
| <i>o</i> -Phenylenediamine                             | 3.1 to 4.4   | Green to non-fl              | 5                                |
| <i>p</i> -Phenylenediamine                             | 3.1 to 4.4   | Non-fl to orange/yellow      | 5                                |
| Morin (2',4',3,5,7-pentahydroxyflavone)                | 3.1 to 4.4   | Non-fl to green              | 6 (0.2%)                         |
|                                                        | 8 to 9.8     | Green to yellow/green        |                                  |
| Thioflavine S                                          | 3.1 to 4.4   | Dark blue to light blue      | 6 (0.2%)                         |
| Fluorescein                                            | 4.0 to 4.5   | Pink/green to green          | 4 (1%)                           |
| Dichlorofluorescein                                    | 4.0 to 6.6   | Blue green to green          | 1                                |
| $\beta$ -Methylesculetin                               | 4.0 to 6.2   | Non-fl to blue               | 1                                |
|                                                        | 9.0 to 10.0  | Blue to light green          |                                  |
| Quininic acid                                          | 4.0 to 5.0   | Yellow to blue               | 6 (satd)                         |
| $\beta$ -Naphthoquinoline                              | 4.4 to 6.3   | Blue to non-fl               | 3                                |
| Resorufin (7-oxyphenoxazone)                           | 4.4 to 6.4   | Yellow to orange             |                                  |

Indicator solutions: 1, 1% solution in ethanol; 2, 0.1% solution in ethanol; 3, 0.05% solution in 90% ethanol; 4, sodium or potassium salt in distilled water; 5, 0.2% solution in 70% ethanol; 6, distilled water.

\* Transition point is at higher potential than the tabulated formal potential because the molar absorptivity of the reduced form is very much greater than that of the oxidized form.

† *Trans* = first noticeable color transition; often 60 mV less than  $E^\circ$

‡ Values of  $E^\circ$  are obtained by extrapolation from measurements in weakly acid or weakly alkaline systems.

8.6 ELECTRODE POTENTIALS

TABLE 8.27 Potentials of the Elements and Their Compounds at 25°C

Standard potentials are tabulated except when a solution composition is stated; the latter are formal potentials and the concentrations are in mol/liter.

| Half-reaction                                                                              | Standard or formal potential | Solution composition |

**TABLE 8.31** Half-Wave Potentials (vs. Saturated Calomel Electrode) of Organic Compounds at 25°C

The solvent systems in this table are listed below:

A, acetonitrile and a perchlorate salt such as  $\text{LiClO}_4$  or a tetraalkyl ammonium salt

B, acetic acid and an alkali acetate, often plus a tetraalkyl ammonium iodide

C, 0.05 to 0.175M tetraalkyl ammonium halide and 75% 1,4-dioxane

D, buffer plus 50% ethanol (EtOH)

**Abbreviations Used in the Table**

|               |                |
|---------------|----------------|
| Bu, butyl     | Me, methyl     |
| Et, ethyl     | MeOH, methanol |
| EtOH, ethanol | PrOH, propanol |
| M, molar      |                |

| Compound                                    | Solvent system                        | $E_{1/2}$           |
|---------------------------------------------|---------------------------------------|---------------------|

**TABLE 8.33** Standard Solutions for Calibrating Conductivity Vessels

The values of conductivity  $\kappa$  are corrected for the conductivity of the water used. The cell constant  $\theta$  of a conductivity cell can be obtained from the equation

$$\theta = \frac{\kappa R R_{\text{solv}}}{R_{\text{solv}} - R}$$

where  $R$  is the resistance measured when the cell is filled with a solution of the composition stated in the table below, and  $R_{\text{solv}}$  is the resistance when the cell is filled with solvent at the same temperature.

| Grams KCl per Kilogram<br>Solution (in vacuo) | Conductivity in $\text{ohm}^{-1} \cdot \text{cm}^{-1}$ at |                          |                          |

**TABLE 8.35** Equivalent Conductivities of Electrolytes in Aqueous Solutions at 18°C

The unit of  $\Lambda$  in the table is  $\Omega^{-1} \cdot \text{cm}^{-2} \cdot \text{equiv}^{-1}$ . The entities to which the equivalent relates are given in the first column.

| Electrolyte                                                          | Concentration, $N$ |       |       |      |      |      |      |      |      |      |      |

8.7.1 Common Conductance Relations\*

*Conductivity.* The standard unit of conductance is electrolytic conductivity (formerly called specific conductance)  $\kappa$ , which is defined as the reciprocal of the resistance [ $\Omega^{-1}$ ] of a 1-m cube of liquid at a specified temperature [ $\Omega^{-1} \cdot \text{m}^{-1}$ ]. See Table 8.33 and the definition of the cell constant.

In accurate work at low concentrations it is necessary to subtract the conductivity of the pure solvent (Table 8.34) from that of the solution to obtain the conductivity due to the electrolyte.

*Resistivity (Specific Resistance)*

$$\rho = \frac{1}{\kappa} \quad [\Omega \cdot \text{m}]$$

\* SI units are in brackets.

*Conductance of an Electrolyte Solution*

$$\frac{1}{R} = \kappa \frac{S}{d} \quad [\Omega^{-1}]$$

where  $S$  is the surface area of the electrode, or the mean cross-sectional area of the solution [ $\text{m}^2$ ], and  $d$  is the mean distance between the electrodes [ $\text{m}$ ].

*Equivalent Conductivity*

$$\Lambda = \frac{\kappa}{C} \quad [\Omega^{-1} \cdot \text{m}^2 \cdot \text{equiv}^{-1}]$$

In the older literature,  $C$  is the concentration in equivalents per liter. The volume of the solution in cubic centimeters per equivalent is equal to  $1000/C$ , and  $\Lambda = 1000 \kappa/C$ , the units employed in Table 8.32 [ $\Omega^{-1} \cdot \text{cm}^2 \cdot \text{equiv}^{-1}$ ]. The formula unit used in expressing the concentration must be specified; for example,  $\text{NaCl}$ ,  $\frac{1}{2}\text{K}_2\text{SO}_4$ ,  $\frac{1}{3}\text{LaCl}_3$ .

The equivalent conductivity of an electrolyte is the sum of contributions of the individual ions. At infinite dilution:  $\Lambda^\circ = \lambda_c^\circ + \lambda_a^\circ$ , where  $\lambda_c^\circ$  and  $\lambda_a^\circ$  are the ionic conductances of cations and anions, respectively, at infinite dilution (Table 8.35).

*Ionic Mobility and Ionic Equivalent Conductivity*

$$\lambda_c = Fu_c \quad \text{and} \quad \lambda_a = Fu_a \quad [\Omega^{-1} \cdot \text{m}^2 \cdot \text{equiv}^{-1}]$$

where  $F$  is the Faraday constant, and  $u_c$ ,  $u_a$  are the ionic mobilities [ $\text{m}^2 \cdot \text{s}^{-1} \cdot \text{V}^{-1}$ ].

$$\Lambda = \alpha F(u_c + u_a) = \alpha(\lambda_c + \lambda_a)$$

where  $\alpha$  is the degree of electrolytic dissociation,  $\Lambda/\Lambda^\circ$ . The electric mobility  $u$  of a species is the magnitude of the velocity in an electric field [ $\text{m} \cdot \text{s}^{-1}$ ] divided by the magnitude of the strength of the electric field  $E$  [ $\text{V} \cdot \text{m}^{-1}$ ].

*Ostwald Dilution Law*

$$K_d = \frac{\alpha^2 C}{1 - \alpha}$$

where  $K_d$  is the dissociation constant of the weak electrolyte. In general for an electrolyte which yields  $n$  ions:

$$K_d = \frac{C^{(n-1)}\Lambda^n}{\Lambda^\circ(n-1)(\Lambda^\circ - \Lambda)}$$

*Transference Numbers or Hittorf Transport Numbers*

$$T_c = \frac{\lambda_c}{\lambda_c + \lambda_a} \quad T_a = \frac{\lambda_a}{\lambda_c + \lambda_a} \quad T_c + T_a = 1$$

$$\frac{T_c}{T_a} = \frac{u_c}{u_a} = \frac{\lambda_c}{\lambda_a}$$

$$\lambda_c = T_c \Lambda \quad \lambda_a = T_a \Lambda$$

## 9.1 LINEAR FREE ENERGY RELATIONSHIPS

Many equilibrium and rate processes can be systematized when the influence of each substituent on the reactivity of substrates is assigned a characteristic constant  $\sigma$  and the reaction parameter  $\rho$  is known or can be calculated. The Hammett equation

$$\log \frac{K}{K^\circ} = \sigma \rho$$

describes the behavior of many *meta*- and *para*-substituted aromatic species. In this equation  $K^\circ$  is the acid dissociation constant of the reference in aqueous solution at 25°C and  $K$  is the corresponding constant for the substituted acid. Separate sigma values are defined by this reaction for *meta* and *para* substituents and provide a measure of the total electronic influence (polar, inductive, and resonance effects) in the absence of conjugation effects. Sigma constants are not valid of substituents *ortho* to the reaction center because of anomalous (mainly steric) effects. The inductive effect is transmitted about equally to the *meta* and *para* positions. Consequently,  $\sigma_m$  is an approximate measure of the size of the inductive effect of a given substituent and  $\sigma_p - \sigma_m$  is an approximate measure of a substituent's resonance effect. Values of Hammett sigma constants are listed in Table 9.1.

Taft sigma values  $\sigma^*$  perform a similar function with respect to aliphatic and alicyclic systems. Values of  $\sigma^*$  are listed in Table 9.1.

The reaction parameter  $\rho$  depends upon the reaction series but not upon the substituents employed. Values of the reaction parameter for some aromatic and aliphatic systems are given in Tables 9.2 and 9.3.

Since substituent effects in aliphatic systems and in *meta* positions in aromatic systems are essentially inductive in character,  $\sigma^*$  and  $\sigma_m$  values are often related by the expression  $\sigma_m = 0.217\sigma^* - 0.106$ . Substituent effects fall off with increasing distance from the reaction center; generally a factor of 0.36 corresponds to the interposition of a  $-\text{CH}_2-$  group, which enables  $\sigma^*$  values to be estimated for  $\text{R}-\text{CH}_2-$  groups not otherwise available.

\*  $\sigma^*$  for  $R_1CO$  and  $R_2$ .

Two modified sigma constants have been formulated for situations in which the substituent enters into resonance with the reaction center in an electron-demanding transition state ( $\sigma^+$ ) or for an electron-rich transition state ( $\sigma^-$ ).  $\sigma^-$  constants give better correlations in reactions involving phenols, anilines, and pyridines and in nucleophilic substitutions. Values of some modified sigma constants are given in Table 9.4.

TABLE 9.4 Special Hammett Sigma Constants

| Substituent                          | $\sigma_m^+$ | $\sigma_p^+$ | $\sigma_p^-$ |

## 10.1 POLYMERS

---

Polymers are mixtures of macromolecules with similar structures and molecular weights that exhibit some average characteristic properties. In some polymers long segments of linear polymer chains are oriented in a regular manner with respect to one another. Such polymers have many of the physical characteristics of crystals and are said to be *crystalline*. Polymers that have polar functional groups show a considerable tendency to be crystalline. Orientation is aided by alignment of dipoles on different chains. Van der Waals' interactions between long hydrocarbon chains may provide sufficient total attractive energy to account for a high degree of regularity within the polymers.

Irregularities such as branch points, comonomer units, and cross-links lead to *amorphous* polymers. They do not have true melting points but instead have glass transition temperatures at which the rigid and glasslike material becomes a viscous liquid as the temperature is raised.

**Elastomers.** Elastomers is a generic name for polymers that exhibit rubberlike elasticity. Elastomers are soft yet sufficiently elastic that they can be stretched several hundred percent under tension. When the stretching force is removed, they retract rapidly and recover their original dimensions.

Polymers that soften or melt and then solidify and regain their original properties on cooling are called *thermoplastic*. A thermoplastic polymer is usually a single strand of linear polymer with few if any cross-links.

**Thermosetting Polymers.** Polymers that soften or melt on warming and then become infusible solids are called *thermosetting*. The term implies that thermal decomposition has not taken place. Thermosetting plastics contain a cross-linked polymer network that extends through the finished article, making it stable to heat and insoluble in organic solvents. Many molded plastics are shaped while molten and are then heated further to become rigid solids of desired shapes.

**Synthetic Rubbers.** Synthetic rubbers are polymers with rubberlike characteristics that are prepared from dienes or olefins. Rubbers with special properties can also be prepared from other polymers, such as polyacrylates, fluorinated hydrocarbons, and polyurethanes.

**Structural Differences.** Polymers exhibit structural differences. A *linear* polymer consists of long segments of single strands that are oriented in a regular manner with respect to one another. *Branched* polymers have substituents attached to the repeating units that extend the polymer laterally. When these units participate in chain propagation and link together chains, a *cross-linked* polymer is formed. A *ladder* polymer results when repeating units have a tetravalent structure such that a polymer consists of two backbone chains regularly cross-linked at short intervals.

Generally polymers involve bonding of the most substituted carbon of one monomeric unit to the least substituted carbon atom of the adjacent unit in a *head-to-tail* arrangement. Substituents appear on alternate carbon atoms. *Tacticity* refers to the configuration of substituents relative to the backbone axis. In an *isotactic* arrangement, substituents are on the same plane of the backbone axis; that is, the configuration at each chiral center is identical.

In a *syndiotactic* arrangement, the substituents are in an ordered alternating sequence, appearing alternately on one side and then on the other side of the chain, thus

In an *atactic* arrangement, substituents are in an unordered sequence along the polymer chains.

**Copolymerization.** Copolymerization occurs when a mixture of two or more monomer types polymerizes so that each kind of monomer enters the polymer chain. The fundamental structure resulting from copolymerization depends on the nature of the monomers and the relative rates of monomer reactions with the growing polymer chain. A tendency toward alternation of monomer units is common.

Random copolymerization is rather unusual. Sometimes a monomer which does not easily form a homopolymer will readily add to a reactive group at the end of a growing polymer chain. In turn, that monomer tends to make the other monomer much more reactive.

In *graft copolymers* the chain backbone is composed of one kind of monomer and the branches are made up of another kind of monomer.

The structure of a *block copolymer* consists of a homopolymer attached to chains of another homopolymer.

Configurations around any double bond give rise to *cis* and *trans* stereoisomerism.

## 10.2 ADDITIVES TO POLYMERS

---

### 10.2.1 Antioxidants

Antioxidants markedly retard the rate of autoxidation throughout the useful life of the polymer. Chain-terminating antioxidants have a reactive  $\text{—NH}$  or  $\text{—OH}$  functional group and include compounds such as secondary aryl amines or hindered phenols. They function by transfer of hydrogen to free radicals, principally to peroxy radicals. Butylated hydroxytoluene is a widely used example.

Peroxide-decomposing antioxidants destroy hydroperoxides, the sources of free radicals in polymers. Phosphites and thioesters such as tris(nonylphenyl) phosphite, distearyl pentaerythritol diphosphite, and dialkyl thiodipropionates are examples of peroxide-decomposing antioxidants.

### 10.2.2 Antistatic Agents

External antistatic agents are usually quaternary ammonium salts of fatty acids and ethoxylated glycerol esters of fatty acids that are applied to the plastic surface. Internal antistatic agents are compounded into plastics during processing. Carbon blacks provide a conductive path through the bulk of the plastic. Other types of internal agents must bloom to the surface after compounding in order to be active. These latter materials are ethoxylated fatty amines and ethoxylated glycerol esters of fatty acids, which often must be individually selected to match chemically each plastic type.

Antistatic agents require ambient moisture to function. Consequently their effectiveness is dependent on the relative humidity. They provide a broad range of protection at 50% relative humidity. Much below 20% relative humidity, only materials which provide a conductive path through the bulk of the plastic to ground (such as carbon black) will reduce electrostatic charging.

### 10.2.3 Chain-Transfer Agents

Chain-transfer agents are used to regulate the molecular weight of polymers. These agents react with the developing polymer and interrupt the growth of a particular chain. The products, however, are free radicals that are capable of adding to monomers and initiating the formation of new chains. The overall effect is to reduce the average molecular weight of the polymer without reducing the rate of polymerization. Branching may occur as a result of chain transfer between a growing but rather short chain with another and longer polymer chain. Branching may also occur if the radical end of a growing chain abstracts a hydrogen from a carbon atom four or five carbons removed from the end. Thiols are commonly used as chain-transfer agents.

### 10.2.4 Coupling Agents

Coupling agents are molecular bridges between the interface of an inorganic surface (or filler) and an organic polymer matrix. Titanium-derived coupling agents interact with the free protons at the inorganic interface to form organic monomolecular layers on the inorganic surface. The titanate-coupling-agent molecule has six functions:

where

| Type       | <i>m</i> | <i>n</i> |
|------------|----------|----------|
| Monoalkoxy | 1        | 3        |
| Coordinate | 4        | 2        |
| Chelate    | 1        | 2        |

Function 1 is the attachment of the hydrolyzable portion of the molecule to the surface of the inorganic (or proton-bearing) species.

Function 2 is the ability of the titanate molecule to transesterify.

Function 3 affects performance as determined by the chemistry of alkylate, carboxyl, sulfonyl, phenolic, phosphate, pyrophosphate, and phosphite groups.

Function 4 provides van der Waals' entanglement via long carbon chains.

Function 5 provides thermoset reactivity via functional groups such as methacrylates and amines.

Function 6 permits the presence of two or three pendent organic groups. This allows all functionality to be controlled to the first-, second-, or third-degree levels.

Silane coupling agents are represented by the formula

where Y represents a hydrolyzable group (typically alkoxy); Z is a functional organic group, such as amino, methacryloxy, epoxy; and R typically is a small aliphatic linkage that serves to attach the functional organic group to silicon in a stable fashion. Bonding to surface hydroxy groups of inorganic compounds is accomplished by the —SiY<sub>3</sub> portion, either by direct bonding of this group or more commonly via its hydrolysis product —Si(OH)<sub>3</sub>. Subsequent reaction of the functional organic group with the organic matrix completes the coupling reaction and establishes a covalent chemical bond from the organic phase through the silane coupling agent to the inorganic phase.

### 10.2.5 Flame Retardants

Flame retardants are thought to function via several mechanisms, dependent upon the class of flame retardant used. Halogenated flame retardants are thought to function principally in the vapor phase either as a diluent and heat sink or as a free-radical trap that stops or slows flame propagation. Phosphorus compounds are thought to function in the solid phase by forming a glaze or coating over the substrate that prevents the heat and mass transfer necessary for sustained combustion. With some additives, as the temperature is increased, the flame retardant acts as a solvent for the polymer, causing it to melt at lower temperatures and flow away from the ignition source.

Mineral hydrates, such as alumina trihydrate and magnesium sulfate heptahydrate, are used in highly filled thermoset resins.

### 10.2.6 Foaming Agents (Chemical Blowing Agents)

Foaming agents are added to polymers during processing to form minute gas cells throughout the product. Physical foaming agents include liquids and gases. Compressed nitrogen is often used in

injection molding. Common liquid foaming agents are short-chain aliphatic hydrocarbons in the C<sub>5</sub> to C<sub>7</sub> range and their chlorinated or fluorinated analogs.

The chemical foaming agent used varies with the temperature employed during processing. At relatively low temperatures (15 to 200°C), the foaming agent is often 4,4'-oxybis-(benzenesulfonylhydrazide) or *p*-toluenesulfonylhydrazide. In the midrange (160 to 232°C), either sodium hydrogen carbonate or 1,1'-azobisformamide is used. For the high range (200 to 285°C), there are *p*-toluenesulfonyl semicarbazide, 5-phenyltetrazole and analogs, and trihydrazinotriazine.

10.2.7 Inhibitors

Inhibitors slow or stop polymerization by reacting with the initiator or the growing polymer chain. The free radical formed from an inhibitor must be sufficiently unreactive that it does not function as a chain-transfer agent and begin another growing chain. Benzoquinone is a typical free-radical chain inhibitor. The resonance-stabilized free radical usually dimerizes or disproportionates to produce inert products and end the chain process.

10.2.8 Lubricants

Materials such as fatty acids are added to reduce the surface tension and improve the handling qualities of plastic films.

TABLE 10.1 Plastic Families

|                                                                      |                                                                                          |

### 10.2.9 Plasticizers

Plasticizers are relatively nonvolatile liquids which are blended with polymers to alter their properties by intrusion between polymer chains. Diisooctyl phthalate is a common plasticizer. A plasticizer must be compatible with the polymer to avoid bleeding out over long periods of time. Products containing plasticizers tend to be more flexible and workable.

### 10.2.10 Ultraviolet Stabilizers

2-Hydroxybenzophenones represent the largest and most versatile class of ultraviolet stabilizers that are used to protect materials from the degradative effects of ultraviolet radiation. They function by absorbing ultraviolet radiation and by quenching electronically excited states.

Hindered amines, such as 4-(2,2,6,6-tetramethylpiperidinyl) decanedioate, serve as radical scavengers and will protect thin films under conditions in which ultraviolet absorbers are ineffective. Metal salts of nickel, such as dibutyldithiocarbamate, are used in polyolefins to quench singlet oxygen or electronically excited states of other species in the polymer. Zinc salts function as peroxide decomposers.

### 10.2.11 Vulcanization and Curing

Originally, vulcanization implied heating natural rubber with sulfur, but the term is now also employed for curing polymers. When sulfur is employed, sulfide and disulfide cross-links form between polymer chains. This provides sufficient rigidity to prevent *plastic flow*. Plastic flow is a process in which coiled polymers slip past each other under an external deforming force; when the force is released, the polymer chains do not completely return to their original positions.

Organic peroxides are used extensively for the curing of unsaturated polyester resins and the polymerization of monomers having vinyl unsaturation. The —O—O— bond is split into free radicals which can initiate polymerization or cross-linking of various monomers or polymers.

### 10.3 FORMULAS AND KEY PROPERTIES OF PLASTIC MATERIALS

---

#### 10.3.1 Acetals

**10.3.1.1 Homopolymer.** Acetal homopolymers are prepared from formaldehyde and consist of high-molecular-weight linear polymers of formaldehyde.

The good mechanical properties of this homopolymer result from the ability of the oxymethylene chains to pack together into a highly ordered crystalline configuration as the polymers change from the molten to the solid state.

Key properties include high melt point, strength and rigidity, good frictional properties, and resistance to fatigue. Higher molecular weight increases toughness but reduces melt flow.

**10.3.1.2 Copolymer.** Acetal copolymers are prepared by copolymerization of 1,3,5-trioxane with small amounts of a comonomer. Carbon-carbon bonds are distributed randomly in the polymer chain. These carbon-carbon bonds help to stabilize the polymer against thermal, oxidative, and acidic attack.

#### 10.3.2 Acrylics

**10.3.2.1 Poly(methyl Methacrylate).** The monomer used for poly(methyl methacrylate), 2-hydroxy-2-methylpropanenitrile, is prepared by the following reaction:

2-Hydroxy-2-methylpropanenitrile is then reacted with methanol (or other alcohol) to yield methacrylate ester. Free-radical polymerization is initiated by peroxide or azo catalysts and produce poly(methyl methacrylate) resins having the following formula:

Key properties are improved resistance to heat, light, and weathering. This polymer is unaffected by most detergents, cleaning agents, and solutions of inorganic acids, alkalies, and aliphatic hydrocarbons. Poly(methyl methacrylate) has light transmittance of 92% with a haze of 1 to 3% and its clarity is equal to glass.

**10.3.2.2 Poly(methyl Acrylate).** The monomer used for preparing poly(methyl acrylate) is produced by the oxidation of propylene. The resin is made by free-radical polymerization initiated by peroxide or azo catalysts and has the following formula:

Resins vary from soft, elastic, film-forming materials to hard plastics.

**10.3.2.3 Poly(acrylic Acid) and Poly(methacrylic Acid).** Glacial acrylic acid and glacial methacrylic acid can be polymerized to produce water-soluble polymers having the following structures:

These monomers provide a means for introducing carboxyl groups into copolymers. In copolymers these acids can improve adhesion properties, improve freeze-thaw and mechanical stability of polymer dispersions, provide stability in alkalies (including ammonia), increase resistance to attack by oils, and provide reactive centers for cross-linking by divalent metal ions, diamines, or epoxides.

**10.3.2.4 Functional Group Methacrylate Monomers.** Hydroxyethyl methacrylate and dimethylaminoethyl methacrylate produce polymers having the following formulas:

The use of hydroxyethyl (also hydroxypropyl) methacrylate as a monomer permits the introduction of reactive hydroxyl groups into the copolymers. This offers the possibility for subsequent cross-linking with an HO-reactive difunctional agent (diisocyanate, diepoxide, or melamine-formaldehyde resin). Hydroxyl groups promote adhesion to polar substrates.

Use of dimethylaminoethyl (also *tert*-butylaminoethyl) methacrylate as a monomer permits the introduction of pendent amino groups which can serve as sites for secondary cross-linking, provide a way to make the copolymer acid-soluble, and provide anchoring sites for dyes and pigments.

**10.3.2.5 Poly(acrylonitrile).** Poly(acrylonitrile) polymers have the following formula:

### 10.3.3 Alkyds

Alkyds are formulated from polyester resins, cross-linking monomers, and fillers of mineral or glass. The unsaturated polyester resins used for thermosetting alkyds are the reaction products of polyfunctional organic alcohols (glycols) and dibasic organic acids.

Key properties of alkyds are dimensional stability, colorability, and arc track resistance. Chemical resistance is generally poor.

### 10.3.4 Alloys

Polymer alloys are physical mixtures of structurally different homopolymers or copolymers. The mixture is held together by secondary intermolecular forces such as dipole interaction, hydrogen bonding, or van der Waals' forces.

Homogeneous alloys have a single glass transition temperature which is determined by the ratio of the components. The physical properties of these alloys are averages based on the composition of the alloy.

Heterogeneous alloys can be formed when graft or block copolymers are combined with a compatible polymer. Alloys of incompatible polymers can be formed if an interfacial agent can be found.

### 10.3.5 Allyls

**10.3.5.1 Diallyl Phthalate (and Diallyl 1,3-Phthalate).** These allyl polymers are prepared from

These resulting polymers are solid, linear, internally cyclized, thermoplastic structures containing unreacted allylic groups spaced at regular intervals along the polymer chain.

Molding compounds with mineral, glass, or synthetic fiber filling exhibit good electrical properties under high humidity and high temperature conditions, stable low-loss factors, high surface and volume resistivity, and high arc and track resistance.

### 10.3.6 Cellulosics

**10.3.6.1 Cellulose Triacetate.** Cellulose triacetate is prepared according to the following reaction:

Because cellulose triacetate has a high softening temperature, it must be processed in solution. A mixture of dichloromethane and methanol is a common solvent.

Cellulose triacetate sheeting and film have good gauge uniformity and good optical clarity. Cellulose triacetate products have good dimensional stability and resistance to water and have good folding endurance and burst strength. It is highly resistant to solvents such as acetone. Cellulose triacetate products have good heat resistance and a high dielectric constant.

**10.3.6.2 Cellulose Acetate, Propionate, and Butyrate.** Cellulose acetate is prepared by hydrolyzing the triester to remove some of the acetyl groups; the plastic-grade resin contains 38 to 40%

These cellulose esters form tough, strong, stiff, hard plastics with almost unlimited color possibilities. Articles made from these plastics have a high gloss and are suitable for use in contact with food.

$$\text{C}_6\text{H}_{10}\text{O}_5 + \text{HNO}_3 \rightarrow [-\text{C}_6\text{H}_7\text{O}_2(\text{OH})(\text{ONO}_2)_2-]_n$$

Key properties of cellulose nitrate are good dimensional stability, low water absorption, and toughness. Its disadvantages are its flammability and lack of stability to heat and sunlight.

Although not as resistant as cellulose esters to acids, it is much more resistant to bases. An outstanding feature is its toughness at low temperatures.

**10.3.6.5 Rayon.** Viscose rayon is obtained by reacting the hydroxy groups of cellulose with carbon disulfide in the presence of alkali to give xanthates. When this solution is poured (spun) into an acid medium, the reaction is reversed and the cellulose is regenerated (coagulated).

### 10.3.7 Epoxy

$$\text{CH}_2\text{---CH---CH}_2\text{Cl} + \text{HO---C}_6\text{H}_4\text{---C(CH}_3)_2\text{---C}_6\text{H}_4\text{---OH} \xrightarrow{\text{aq NaOH}}$$

**Bisphenol A**

$$\text{CH}_2\text{---CH---CH}_2\text{---}\left(\text{O---C}_6\text{H}_4\text{---C(CH}_3)_2\text{---C}_6\text{H}_4\text{---O---CH}_2\text{---CH(OH)---CH}_2\right)_n$$

Epoxy novolac resins are produced by glycidation of the low-molecular-weight reaction products of phenol (or cresol) with formaldehyde. Highly cross-linked systems are formed that have superior performance at elevated temperatures.

### 10.3.8 Fluorocarbon

**10.3.8.1 Poly(tetrafluoroethylene).** Poly(tetrafluoroethylene) is prepared from tetrafluoroethylene and consists of repeating units in a predominantly linear chain:

Tetrafluoroethylene polymer has the lowest coefficient of friction of any solid. It has remarkable chemical resistance and a very low brittleness temperature ( $-100^\circ\text{C}$ ). Its dielectric constant and loss factor are low and stable across a broad temperature and frequency range. Its impact strength is high.

**10.3.8.2 Fluorinated Ethylene-Propylene Resin.** Polymer molecules of fluorinated ethylene-propylene consist of predominantly linear chains with this structure:

Key properties are its flexibility, translucency, and resistance to all known chemicals except molten alkali metals, elemental fluorine and fluorine precursors at elevated temperatures, and concentrated perchloric acid. It withstands temperatures from  $-270^\circ$  to  $250^\circ\text{C}$  and may be sterilized repeatedly by all known chemical and thermal methods.

**10.3.8.3 Perfluoroalkoxy Resin.** Perfluoroalkoxy resin has the following formula:

It resembles polytetrafluoroethylene and fluorinated ethylene propylene in its chemical resistance, electrical properties, and coefficient of friction. Its strength, hardness, and wear resistance are about equal to the former plastic and superior to that of the latter at temperatures above  $150^\circ\text{C}$ .

**10.3.8.4 Poly(vinylidene Fluoride).** Poly(vinylidene fluoride) consists of linear chains in which the predominant repeating unit is

It has good weathering resistance and does not support combustion. It is resistant to most chemicals and solvents and has greater strength, wear resistance, and creep resistance than the preceding three fluorocarbon resins.

**10.3.8.5 Poly(1-Chloro-1,2,2-Trifluoroethylene).** Poly(1-chloro-1,2,2-trifluoroethylene) consists of linear chains in which the predominant repeating unit is

It possesses outstanding barrier properties to gases, especially water vapor. It is surpassed only by the fully fluorinated polymers in chemical resistance. A few solvents dissolve it at temperatures

above 100°C, and it is swollen by a number of solvents, especially chlorinated solvents. It is harder and stronger than perfluorinated polymers, and its impact strength is lower.

**10.3.8.6 Ethylene-Chlorotrifluoroethylene Copolymer.** Ethylene-chlorotrifluoroethylene copolymer consists of linear chains in which the predominant 1 : 1 alternating copolymer is

This copolymer has useful properties from cryogenic temperatures to 180°C. Its dielectric constant is low and stable over a broad temperature and frequency range.

**10.3.8.7 Ethylene-Tetrafluoroethylene Copolymer.** Ethylene-tetrafluoroethylene copolymer consists of linear chains in which the repeating unit is

Its properties resemble those of ethylene-chlorotrifluoroethylene copolymer.

**10.3.8.8 Poly(vinyl Fluoride).** Poly(vinyl fluoride) consists of linear chains in which the repeating unit is

It is used only as a film, and it has good resistance to abrasion and resists staining. It also has outstanding weathering resistance and maintains useful properties from -100 to 150°C.

### 10.3.9 Nitrile Resins

The principal monomer of nitrile resins is acrylonitrile (see “Polyacrylonitrile”), which constitutes about 70% by weight of the polymer and provides the polymer with good gas barrier and chemical resistance properties. The remainder of the polymer is 20 to 30% methylacrylate (or styrene), with 0 to 10% butadiene to serve as an impact-modifying monomer.

### 10.3.10 Melamine Formaldehyde

The monomer used for preparing melamine formaldehyde is formed as follows:

Hexamethylolmelamine can further condense in the presence of an acid catalyst; ether linkages can also form (see “Urea Formaldehyde”). A wide variety of resins can be obtained by careful selection of pH, reaction temperature, reactant ratio, amino monomer, and extent of condensation. Liquid coating resins are prepared by reacting methanol or butanol with the initial methylolated products. These can be used to produce hard, solvent-resistant coatings by heating with a variety of hydroxy, carboxyl, and amide functional polymers to produce a cross-linked film.

### 10.3.11 Phenolics

**10.3.11.1 Phenol-Formaldehyde Resin.** Phenol-formaldehyde resin is prepared as follows:

**One-Stage Resins.** The ratio of formaldehyde to phenol is high enough to allow the thermosetting process to take place without the addition of other sources of cross-links.

**Two-Stage Resins.** The ratio of formaldehyde to phenol is low enough to prevent the thermosetting reaction from occurring during manufacture of the resin. At this point the resin is termed *novolac* resin. Subsequently, hexamethylenetetramine is incorporated into the material to act as a source of chemical cross-links during the molding operation (and conversion to the thermoset or cured state).

### 10.3.12 Polyamides

**10.3.12.1 Nylon 6, 11, and 12.** This class of polymers is polymerized by addition reactions of ring compounds that contain both acid and amine groups on the monomer.

Nylon 6 is polymerized from 2-oxohexamethyleneimine (6 carbons); nylon 11 and 12 are made this way from 11- and 12-carbon rings, respectively.

**10.3.12.2 Nylon 6/6, 6/9, and 6/12.** As illustrated below, nylon 6/6 is polymerized from 1,6-hexanedioic acid (six carbons) and 1,6-hexanediamine (six carbons).

Other nylons are made this way from direct combinations of monomers to produce types 6/9, 6/10, and 6/12.

Nylon 6 and 6/6 possess the maximum stiffness, strength, and heat resistance of all the types of nylon. Type 6/6 has a higher melt temperature, whereas type 6 has a higher impact resistance and better processibility. At a sacrifice in stiffness and heat resistance, the higher analogs of nylon are useful primarily for improved chemical resistance in certain environments (acids, bases, and zinc chloride solutions) and for lower moisture absorption.

Aromatic nylons,  $[-\text{NH}-\text{C}_6\text{H}_4-\text{CO}-]_n$  (also called aramids), have specialty uses because of their improved clarity.

### 10.3.13 Poly(amide-imide)

Poly(amide-imide) is the condensation polymer of 1,2,4-benzenetricarboxylic anhydride and various aromatic diamines and has the general structure:

It is characterized by high strength and good impact resistance, and retains its physical properties at temperatures up to 260°C. Its radiation (gamma) resistance is good.

### 10.3.14 Polycarbonate

Polycarbonate is a polyester in which dihydric (or polyhydric) phenols are joined through carbonate linkages. The general-purpose type of polycarbonate is based on 2,2-bis(4'-hydroxybenzene)propane (bisphenol A) and has the general structure:

Polycarbonates are the toughest of all thermoplastics. They are window-clear, amazingly strong and rigid, autoclavable, and nontoxic. They have a brittleness temperature of -135°C.

### 10.3.15 Polyester

**10.3.15.1 Poly(butylene Terephthalate).** Poly(butylene terephthalate) is prepared in a condensation reaction between dimethyl terephthalate and 1,4-butanediol and its repeating unit has the general structure

This thermoplastic shows good tensile strength, toughness, low water absorption, and good frictional properties, plus good chemical resistance and electrical properties.

**10.3.15.2 Poly(ethylene Terephthalate).** Poly(ethylene terephthalate) is prepared by the reaction of either terephthalic acid or dimethyl terephthalate with ethylene glycol, and its repeating unit has the general structure.

A key property is its chemical inertness. Strong oxidizing agents eventually cause some oxidation, and some solvents cause softening or swelling, but there is no known solvent for polyethylene at room temperature. The brittleness temperature is  $-100^{\circ}\text{C}$  for both types. Polyethylene has good low-temperature toughness, low water absorption, and good flexibility at subzero temperatures.

**10.3.17.2 Polypropylene.** The polymerization of propylene results in a polymer with the following structure:

The desired form in homopolymers is the isotactic arrangement (at least 93% is required to give the desired properties). Copolymers have a random arrangement. In block copolymers a secondary reactor is used where active polymer chains can further polymerize to produce segments that use ethylene monomer.

Polypropylene is translucent and autoclavable and has no known solvent at room temperature. It is slightly more susceptible to strong oxidizing agents than polyethylene.

**10.3.17.3 Polybutylene.** Polybutylene is composed of linear chains having an isotactic arrangement of ethyl side groups along the chain backbone.

It has a helical conformation in the stable crystalline form.

Polybutylene exhibits high tear, impact, and puncture resistance. It also has low creep, excellent chemical resistance, and abrasion resistance with coilability.

**10.3.17.4 Ionomer.** Ionomer is the generic name for polymers based on sodium or zinc salts of ethylene-methacrylic acid copolymers in which interchain ionic bonding, occurring randomly between the long-chain polymer molecules, produces solid-state properties.

The abrasion resistance of ionomers is outstanding, and ionomer films exhibit optical clarity. In composite structures ionomers serve as a heat-seal layer.

### 10.3.18 Poly(phenylene Sulfide)

Poly(phenylene sulfide) has the following formula:

The recurring *para*-substituted benzene rings and sulfur atoms form a symmetrical rigid backbone.

The high degree of crystallization and the thermal stability of the bond between the benzene ring and sulfur are the two properties responsible for the polymer's high melting point, thermal stability, inherent flame retardance, and good chemical resistance. There are no known solvents of poly(phenylene sulfide) that can function below  $205^{\circ}\text{C}$ .

### 10.3.19 Polyurethane

**10.3.19.1 Foams.** Polyurethane foams are prepared by the polymerization of polyols with isocyanates.

Commonly used isocyanates are toluene diisocyanate, methylene diphenyl isocyanate, and polymeric isocyanates. Polyols used are macroglycols based on either polyester or polyether. The former [poly(ethylene phthalate) or poly(ethylene 1,6-hexanedioate)] have hydroxyl groups that are free to react with the isocyanate. Most flexible foam is made from 80/20 toluene diisocyanate (which refers to the ratio of 2,4-toluene diisocyanate to 2,6-toluene diisocyanate). High-resilience foam contains about 80% 80/20 toluene diisocyanate and 20% poly(methylene diphenyl isocyanate), while semi-flexible foam is almost always 100% poly(methylene diphenyl isocyanate). Much of the latter reacts by trimerization to form isocyanurate rings.

Flexible foams are used in mattresses, cushions, and safety applications. Rigid and semiflexible foams are used in structural applications and to encapsulate sensitive components to protect them against shock, vibration, and moisture. Foam coatings are tough, hard, flexible, and chemically resistant.

**10.3.19.2 Elastomeric Fiber.** Elastomeric fibers are prepared by the polymerization of polymeric polyols with diisocyanates.

The structure of elastomeric fibers is similar to that illustrated for polyurethane foams.

### 10.3.20 Silicones

Silicones are formed in the following multistage reaction:

The silanols formed above are unstable and under dehydration. On polycondensation, they give polysiloxanes (or silicones) which are characterized by their three-dimensional branched-chain structure. Various organic groups introduced within the polysiloxane chain impart certain characteristics and properties to these resins.

Methyl groups impart water repellency, surface hardness, and noncombustibility.

Phenyl groups impart resistance to temperature variations, flexibility under heat, resistance to abrasion, and compatibility with organic products.

Vinyl groups strengthen the rigidity of the molecular structure by creating easier cross-linkage of molecules.

Methoxy and alkoxy groups facilitate cross-linking at low temperatures.

Oils and gums are nonhighly branched- or straight-chain polymers whose viscosity increases with the degree of polycondensation.

### 10.3.21 Styrenics

**10.3.21.1 Polystyrene.** Polystyrene has the following formula:

Polystyrene is rigid with excellent dimensional stability, has good chemical resistance to aqueous solutions, and is an extremely clear material.

Impact polystyrene contains polybutadiene added to reduce brittleness. The polybutadiene is usually dispersed as a discrete phase in a continuous polystyrene matrix. Polystyrene can be grafted onto rubber particles, which assures good adhesion between the phases.

**10.3.21.2 Acrylonitrile-Butadiene-Styrene (ABS) Copolymers.** This basic three-monomer system can be tailored to yield resins with a variety of properties. Acrylonitrile contributes heat resistance, high strength, and chemical resistance. Butadiene contributes impact strength, toughness, and retention of low-temperature properties. Styrene contributes gloss, processibility, and rigidity. ABS polymers are composed of discrete polybutadiene particles grafted with the styrene-acrylonitrile copolymer; these are dispersed in the continuous matrix of the copolymer.

**10.3.21.3 Styrene-Acrylonitrile (SAN) Copolymers.** SAN resins are random, amorphous copolymers whose properties vary with molecular weight and copolymer composition. An increase in molecular weight or in acrylonitrile content generally enhances the physical properties of the copolymer but at some loss in ease of processing and with a slight increase in polymer color.

SAN resins are rigid, hard, transparent thermoplastics which process easily and have good dimensional stability—a combination of properties unique in transparent polymers.

### 10.3.22 Sulfones

Below are the formulas for three polysulfones.

Polysulfone

Poly(ester sulfone)

Poly(phenyl sulfone)

The isopropylidene linkage imparts chemical resistance, the ether linkage imparts temperature resistance, and the sulfone linkage imparts impact strength. The brittleness temperature of polysulfones is  $-100^\circ\text{C}$ . Polysulfones are clear, strong, nontoxic, and virtually unbreakable. They do not hydrolyze during autoclaving and are resistant to acids, bases, aqueous solutions, aliphatic hydrocarbons, and alcohols.

### 10.3.23 Thermoplastic Elastomers

**10.3.23.1 Polyolefins.** In these thermoplastic elastomers the hard component is a crystalline polyolefin, such as polyethylene or polypropylene, and the soft portion is composed of ethylene-propylene rubber. Attractive forces between the rubber and resin phases serve as labile cross-links. Some contain a chemically cross-linked rubber phase that imparts a higher degree of elasticity.

**10.3.23.2 Styrene-Butadiene-Styrene Block Copolymers.** Styrene blocks associate into domains that form hard regions. The midblock, which is normally butadiene, ethylene-butene, or isoprene blocks, forms the soft domains. Polystyrene domains serve as cross-links.

**10.3.23.3 Polyurethanes.** The hard portion of polyurethane consists of a chain extender and polyisocyanate. The soft component is composed of polyol segments.

**10.3.23.4 Polyesters.** The hard portion consists of copolyester, and the soft portion is composed of polyol segments.

### 10.3.24 Vinyl

**10.3.24.1 Poly(vinyl Chloride) (PVC).** Polymerization of vinyl chloride results in the formation of a polymer with the following formula:

When blended with phthalate ester plasticizers, PVC becomes soft and pliable.

Its key properties are good resistance to oils and a very low permeability to most gases.

**10.3.24.2 Poly(vinyl Acetate).** Poly(vinyl acetate) has the following formula:

Poly(vinyl acetate) is used in latex water paints because of its weathering, quick-drying, recoatability, and self-priming properties. It is also used in hot-melt and solution adhesives.

**10.3.24.3 Poly(vinyl Alcohol).** Poly(vinyl alcohol) has the following formula:

It is used in adhesives, paper coating and sizing, and textile warp size and finishing applications.

**10.3.24.4 Poly(vinyl Butyral).** Poly(vinyl butyral) is prepared according to the following reaction:

Its key characteristics are its excellent optical and adhesive properties. It is used as the interlayer film for safety glass.

**10.3.24.5 Poly(vinylidene Chloride).** Poly(vinylidene chloride) is prepared according to the following reaction:

Random copolymer

### 10.3.25 Urea Formaldehyde

The reaction of urea with formaldehyde yields the following products, which are used as monomers in the preparation of urea formaldehyde resin.

The reaction conditions can be varied so that only one of those monomers is formed. 1-Hydroxymethylurea and 1,3-bis(hydroxymethyl)urea condense in the presence of an acid catalyst to produce urea formaldehyde resins. A wide variety of resins can be obtained by careful selection of the pH, reaction temperature, reactant ratio, amino monomer, and degree of polymerization. If the reaction is carried far enough, an infusible polymer network is produced.

Liquid coating resins are prepared by reacting methanol or butanol with the initial hydroxymethylureas. Ether exchange reactions between the amino resin and the reactive sites on the polymer produce a cross-linked film.

**TABLE 10.2** Properties of Commercial Plastics

| Properties                                                    | Acetal           |                  |                                  |                                |                                                  |

## 10.4 FORMULAS AND ADVANTAGES OF RUBBERS

---

### 10.4.1 Gutta Percha

Gutta percha is a natural polymer of isoprene (3-methyl-1,3-butadiene) in which the configuration around each double bond is *trans*. It is hard and horny and has the following formula:

### 10.4.2 Natural Rubber

Natural rubber is a polymer of isoprene in which the configuration around each double bond is *cis* (or *Z*):

Its principal advantages are high resilience and good abrasion resistance.

### 10.4.3 Chlorosulfonated Polyethylene

Chlorosulfonated polyethylene is prepared as follows:

Cross-linking, which can occur as a result of side reactions, causes an appreciable gel content in the final product.

The polymer can be vulcanized to give a rubber with very good chemical (solvent) resistance, excellent resistance to aging and weathering, and good color retention in sunlight.

#### 10.4.4 Epichlorohydrin

Epichlorohydrin is a product of covulcanization of epichlorohydrin (epoxy) polymers with rubbers, especially *cis*-polybutadiene.

Its advantages include impermeability to air, excellent adhesion to metal, and good resistance to oils, weathering, and low temperature.

#### 10.4.5 Nitrile Rubber (NBR, GRN, Buna N)

Nitrile rubber can be prepared as follows:

Nitrile rubber is also known as nitrile-butadiene rubber (NBR), government rubber nitrile (GRN), and Buna N.

It possesses resistance to oils up to 120°C and excellent abrasion resistance and adhesion to metal.

#### 10.4.6 Polyacrylate

Polyacrylate has the following formula:

It possesses oil and heat resistance to 175°C and excellent resistance to ozone.

#### 10.4.7 *cis*-Polybutadiene Rubber (BR)

*cis*-Polybutadiene is prepared by polymerization of butadiene by mostly 1,4-addition.

The polybutadiene produced is in the *Z* (or *cis*) configuration.

*cis*-Polybutadiene has good abrasion resistance, is useful at low temperature, and has excellent adhesion to metal.

### 10.4.8 Polychloroprene (Neoprene)

Polychloroprene is prepared as follows:

It has very good weathering characteristics, is resistant to ozone and to oil, and is heat-resistant to 100°C.

### 10.4.9 Ethylene-Propylene-Diene Rubber (EPDM)

Ethylene-propylene-diene rubber is polymerized from 60 parts ethylene, 40 parts propylene, and a small amount of nonconjugated diene. The nonconjugated diene permits sulfur vulcanization of the polymer instead of using peroxide.

It is a very lightweight rubber and has very good weathering and electrical properties, excellent adhesion, and excellent ozone resistance.

### 10.4.10 Polyisobutylene (Butyl Rubber)

Polyisobutylene is prepared as follows:

It possesses excellent ozone resistance, very good weathering and electrical properties, and good heat resistance.

### 10.4.11 (Z)-Polyisoprene (Synthetic Natural Rubber)

Polymerization of isoprene by 1,4-addition produces polyisoprene that has a *cis* (or *Z*) configuration.

### 10.4.12 Polysulfide Rubbers

Polysulfide rubbers are prepared as follows:

where R can be

or

Polysulfide rubbers possess excellent resistance to weathering and oils and have very good electrical properties.

### 10.4.13 Poly(vinyl Chloride) (PVC)

Poly(vinyl chloride) as previously discussed in Sec. 10.3, Formulas and Key Properties of Plastic Materials, has the following structures:

PVC polymer plus special plasticizers are used to produce flexible tubing which has good chemical resistance.

### 10.4.14 Silicone Rubbers

Silicone rubbers are prepared as follows:

Other groups may replace the methyl groups.

Silicone rubbers have excellent ozone and weathering resistance, good electrical properties, and good adhesion to metal.

### 10.4.15 Styrene-Butadiene Rubber (GRS, SBR, Buna S)

Styrene-butadiene rubber is prepared from the free-radical copolymerization of one part by weight of styrene and three parts by weight of 1,3-butadiene. The butadiene is incorporated by both 1,4-addition (80%) and 1,2-addition (20%). The configuration around the double bond of the 1,4-adduct is about 80% *trans*. The product is a random copolymer with these general features:

Styrene-butadiene rubber (SBR) is also known as government rubber styrene (GRS) and Buna S.

#### 10.4.16 Urethane

See Table 10.3.

**TABLE 10.3** Properties of Natural and Synthetic Rubbers

| Rubber                                                                         | Specific gravity | Durometer hardness (or Shore) | Ultimate elongation % (23°C) | Tensile strength, lb · in <sup>-2</sup> (23°C) | Service temperature, °C |         |
|--------------------------------------------------------------------------------|------------------|-------------------------------|------------------------------|------------------------------------------------|-------------------------|---------|
|                                                                                |                  |                               |                              |                                                | Minimum                 | Maximum |
| Gutta percha (hard rubber)                                                     | 1.2–1.95         | (65–95)                       | 3–8                          | 4000–10,000                                    |                         | 104     |
| Natural rubber (NR)                                                            | 0.93             | 20–100                        | 750–850                      | 3000–4500                                      | –56                     | 82      |
| Chlorosulfonated polyethylene                                                  | 1.10             | 50–95                         | 100–500                      | 500–3000                                       | –54                     | 121     |
| Epichlorohydrin                                                                | 1.27             | 60–90                         | 100–400                      | 1000–2500                                      | –46                     | 121     |
| Fluoroelastomers                                                               | 1.4–1.95         | 60–90                         | 100–350                      | 2000–3000                                      | –40                     | 232     |

10.5 CHEMICAL RESISTANCE

TABLE 10.4 Resistance of Selected Polymers and Rubbers to Various Chemicals at 20°C

The information in this table is intended to be used only as a general guide. The chemical resistance classifications are E = excellent (30 days of exposure causes no damage), G = good (some damage after 30 days), F = fair (exposure may cause crazing, softening, swelling, or loss of strength), N = not recommended (immediate damage may occur).

|                                                                                   | Chemical              |                                |                     |           |                        |        |        |         |                         |                        |                           |         |                          |

TABLE 10.5 Gas Permeability Constants (10<sup>10</sup> P) at 25°C for Polymers and Rubbers

The gas permeability constant *P* is defined as

$$P = \frac{\text{amount of permeant}}{(\text{area}) \times (\text{time}) \times (\text{driving forced across the film})}$$

The gas permeability constant is the amount of gas expressed in cubic centimeters passed in 1 s through a 1-cm<sup>2</sup> area of film when the pressure across a film thickness of 1 cm is 1 cmHg and the temperature is 25°C. All tabulated values are multiplied by 10<sup>10</sup> and are in units of seconds<sup>-1</sup> (centimeters of Hg)<sup>-1</sup>. Other temperatures are indicated by exponents and are expressed in degrees Celsius.

## 11.1 COOLING

**TABLE 11.1** Cooling Mixtures

The table below gives the lowest temperature that can be obtained from a mixture of the inorganic salt with finely shaved dry ice. With the organic substances, dry ice ( $-78^{\circ}\text{C}$ ) in small lumps can be added to the solvent until a slight excess of dry ice remains or liquid nitrogen ( $-196^{\circ}\text{C}$ ) can be poured into the solvent until a slush is formed that consists of the solid-liquid mixture at its melting point.

| Substance                  | Quantity of substance, g | Quantity of water, mL | Temperature, $^{\circ}\text{C}$ |
|----------------------------|--------------------------|-----------------------|---------------------------------|
| Ammonium nitrate           | 100                      | 94                    | $-4.0$                          |
| Sodium nitrate             | 75                       | 100                   | $-5.3$                          |
| Sodium thiosulfate 5-water | 110                      | 100                   | $-8.0$                          |
| Sodium chloride            | 36                       | 100                   | $-10.0$                         |
| Sodium nitrate             | 50                       | 100                   | $-17.8$                         |
| Sodium bromide             | 66                       | 100                   | $-28$                           |
| Magnesium chloride         | 85                       | 100                   | $-34$                           |
| Calcium chloride 6-water   | 100                      | 81                    | $-40.3$                         |
|                            | 100                      | 70                    | $-55$                           |

| Substance                | Temperature, $^{\circ}\text{C}$ | Substance        | Temperature, $^{\circ}\text{C}$ |
|--------------------------|---------------------------------|------------------|---------------------------------|
| Ethylene glycol          | $-13$                           | Acetone          | $-77$                           |
| 1,2-Dichlorobenzene      | $-17$                           | Ethyl acetate    | $-84$                           |
| Carbon tetrachloride     | $-22.9$                         | 2-Butanone       | $-87$                           |
| Bromobenzene             | $-31$                           | Hexane           | $-95$                           |
| Methoxybenzene           | $-37$                           | Methanol         | $-98$                           |
| Bis(2-ethoxyethyl) ether | $-44$                           | Carbon disulfide | $-112$                          |
| Chlorobenzene            | $-45$                           | Bromoethane      | $-119$                          |
| <i>N</i> -Methylaniline  | $-57$                           | Pentane          | $-130$                          |
| <i>p</i> -Cymene         | $-68$                           | 2-Methylbutane   | $-160$                          |

**TABLE 11.2** Molecular Lowering of the Melting or Freezing Point  
*Cryoscopic constants.*

The cryoscopic constant  $K_f$  gives the depression of the melting point  $\Delta T$  (in degrees Celsius) produced when 1 mol of solute is dissolved in 1000 g of a solvent. It is applicable only to dilute solutions for which the number of moles of solute is negligible in comparison with the number of moles of solvent. It is often used for molecular weight determinations.

$$M_2 = \frac{1000w_2K_f}{w_1 \Delta T}$$

where  $w_1$  is the weight of the solvent and  $w_2$  is the weight of the solute whose molecular weight is  $M_2$ .

| Compound                           | $K_f$ | Compound                                        | $K_f$      |
|------------------------------------|-------|-------------------------------------------------|------------|
| Acetamide                          | 4.04  | Diphenylamine                                   | 8.60       |
| Acetic acid                        | 3.90  | Diphenyl ether                                  | 7.88       |
| Acetone                            | 2.40  | 1,2-Ethanediamine                               | 2.43       |

<sup>a</sup> May form explosive mixtures when contacting organic material. <sup>b</sup> Explosive C<sub>2</sub>H<sub>2</sub> formed. <sup>c</sup> Slow in drying action.  
<sup>d</sup> H<sub>2</sub> formed. <sup>e</sup> Used as column drying of organic liquids. <sup>f</sup> Strong reductant.

A saturated aqueous solution in contact with an excess of a definite solid phase at a given temperature will maintain constant humidity in an enclosed space. Table 11.4 gives a number of salts suitable for this purpose. The aqueous tension (vapor pressure, in millimeters of Hg) of a solution at a given temperature is found by multiplying the decimal fraction of the humidity by the aqueous tension at 100 percent humidity for the specific temperature. For example, the aqueous tension of a saturated solution of NaCl at 20°C is  $0.757 \times 17.54 = 13.28$  mmHg and at 80°C it is  $0.764 \times 355.1 = 271.3$  mmHg.

**TABLE 11.4** Solutions for Maintaining Constant Humidity

| Solid Phase                                                         | % Humidity at Specified Temperatures (°C) |       |       |       |       |       |       |

### 11.3 BOILING POINTS AND HEATING BATHS

**TABLE 11.8** Organic Solvents Arranged by Boiling Points

| Name                     | BP, °C | Name                      | BP, °C |
|--------------------------|--------|---------------------------|--------|
| Ethylene oxide           | 10.6   | 1-Propanol                | 97.2   |
| Chloroethane             | 12.3   | Heptane                   | 98.4   |
| Furan                    | 31.4   | 1-Chloro-3-methylbutane   | 99     |
| Methyl formate           | 31.5   | Ethyl propionate          | 99.1   |
| Diethyl ether            | 34.6   | 2-Butanol                 | 99.6   |
| Propylene oxide          | 34.5   | Formic acid               | 100.8  |
| Pentane                  | 36.1   | Methylcyclohexane         | 100.9  |
| Bromoethane              | 38.4   | 1,4-Dioxane               | 101.2  |
| Dichloromethane          | 39.8   | Nitromethane              | 101.2  |
| Dimethoxymethane         | 42.3   | Propyl acetate            | 101.5  |
| Carbon disulfide         | 46.3   | 2-Pentanone               | 101.7  |
| 1-Isopropoxy-2-propanol  | 47.9   | 3-Pentanone               | 102.0  |
| Ethyl formate            | 54.2   | 2-Methyl-2-butanol        | 102.0  |
| Acetone                  | 56.2   | 1,1-Diethoxyethane        | 102.7  |
| Methyl acetate           | 56.3   | Butyl formate             | 106.6  |
| 1,1-Dichloroethane       | 57.3   | 2-Methyl-1-propanol       | 107.9  |
| Dichloroethylene         | 60.6   | Toluene                   | 110.6  |
| Chloroform               | 61.2   | sec-Butyl acetate         | 112.3  |
| Methanol                 | 64.7   | 1,1,2-Trichloroethane     | 113.5  |
| Tetrahydrofuran          | 66.0   | Nitroethane               | 114.1  |
| Diisopropyl ether        | 68.0   | Pyridine                  | 115.2  |
| Hexane                   | 68.7   | 3-Pentanol                | 115.6  |
| 1-Chloro-2-methylpropane | 68.9   | 4-Methyl-2-pentanone      | 115.7  |
| 1,1,1-Trichloroethane    | 74.0   | 1-Chloro-2,3-epoxypropane | 116.1  |
| 1,3-Dioxolane            | 74–75  | 1-Butanol                 | 117.7  |
| Carbon tetrachloride     | 76.7   | Acetic acid               | 117.9  |
| Ethyl acetate            | 77.1   | Isobutyl acetate          | 118.0  |
| 1-Chlorobutane           | 77.9   | 2-Pentanol                | 119.3  |
| Ethanol                  | 78.3   | 1-Bromo-3-methylbutane    | 119.7  |
| 2-Butanone               | 79.6   | 1-Methoxy-2-propanol      | 120.1  |
| 2-Methyltetrahydrofuran  | 80.0   | 2-Nitropropane            | 120.3  |
| Benzene                  | 80.1   | Tetrachloroethylene       | 121.1  |
| Cyclohexane              | 80.7   | Ethyl butyrate            | 121.6  |
| Propyl formate           | 80.9   | 3-Hexanone                | 123    |
| Acetonitrile             | 81.6   | 2,4-Dimethyl-3-pentanone  | 124    |
| 2-Propanol               | 82.4   | 2-Methoxyethanol          | 124.6  |
| 1,1,-Dimethylethanol     | 82.4   | Octane                    | 125.7  |
| Cyclohexene              | 83.0   | Butyl acetate             | 126.1  |
| Diisopropylamine         | 83.5   | Diethyl carbonate         | 126.8  |
| 1,2-Dichloroethane       | 83.7   | 2-Hexanone                | 127.2  |
| Thiophene                | 84.2   | 1-Chloro-2-propanol       | 127.4  |
| Trichloroethylene        | 87.2   | 2-Chloroethanol           | 128.6  |
| Isopropyl acetate        | 88.2   | 3-Methyl-1-penten-2-one   | 129.5  |
| 1-Bromo-2-methylpropane  | 91.5   | 1-Nitropropane            | 131.2  |
| 2,5-Dimethylfuran        | 93–94  | Chlorobenzene             | 131.7  |
| Ethyl chloroformate      | 94     | 1,2-Dibromoethane         | 131.7  |
| Allyl alcohol            | 96.6   | 4-Methyl-2-pentanol       | 131.7  |
| 1,2-Dichloropropane      | 96.8   |                           |        |

**TABLE 11.8** Organic Solvents Arranged by Boiling Points (*Continued*)

| Name                                       | BP, °C  | Name                               | BP, °C  |
|--------------------------------------------|---------|------------------------------------|---------|
| 3-Methyl-1-butanol                         | 132.0   | 2-Octanol                          | 179     |
| Cyclohexylamine                            | 134.8   | 1,2-Dichlorobenzene                | 180.4   |
| 2-Ethoxyethanol                            | 134.8   | Ethyl acetoacetate                 | 180.8   |
| Ethylbenzene                               | 136.2   | Phenol                             | 181.8   |
| 1-Pentanol                                 | 138     | 2-Ethyl-1-hexanol                  | 184.3   |
| <i>p</i> -Xylene                           | 138.4   | Aniline                            | 184.4   |
| <i>m</i> -Xylene                           | 139.1   | Benzyl ethyl ether                 | 185.0   |
| Acetic anhydride                           | 140.0   | Diethyl oxalate                    | 185.4   |
| 2,4-Pentanedione                           | 140.6   | 1,2-Propanediol                    | 188     |
| Isopentyl acetate                          | 142     | Bis(2-ethoxyethyl) ether           | 188.4   |
| Dibutyl ether                              | 142.4   | Dimethyl sulfoxide                 | 189.0   |
| 4-Heptanone                                | 143.7   | 1,2-Ethanediol diacetate           | 190.2   |
| <i>o</i> -Xylene                           | 144.4   | Benzonitrile                       | 191.0   |
| 2-Methoxyethyl acetate                     | 144.5   | 2,5-Hexanedione                    | 191.4   |
| 1,1,2,2-Tetrachloroethane                  | 146.3   | 2-(2-Methoxyethoxy)-ethanol        | 194.1   |
| 3-Heptanone                                | 147.8   | <i>N,N</i> -Dimethylaniline        | 194.2   |
| Tribromomethane                            | 149.6   | 1-Octanol                          | 195.2   |
| Nonane                                     | 150.8   | 1,2-Ethanediol                     | 197.3   |
| 2-Heptanone                                | 151     | Diethyl malonate                   | 199.3   |
| Isopropylbenzene                           | 152.4   | Methyl benzoate                    | 199.5   |
| <i>N,N</i> -Dimethylformamide              | 153.0   | <i>o</i> -Toluidine                | 200.4   |
| Methoxybenzene                             | 153.8   | <i>p</i> -Toluidine                | 200.6   |
| Ethyl lactate                              | 154.5   | 2-(2-Ethoxyethoxy)-ethanol         | 202     |
| Cyclohexanone                              | 155.7   | Acetophenone                       | 202.1   |
| Bromobenzene                               | 156.2   | 1,2-Dibutoxyethane                 | 203.6   |
| 1,2,3-Trichloropropane                     | 156.9   | 1-Phenylethanol                    | 203.9   |
| 1-Hexanol                                  | 157.5   | <i>m</i> -Toluidine                | 203.4   |
| Propylbenzene                              | 159.2   | Benzyl alcohol                     | 205.5   |
| Cyclohexanol                               | 161.1   | Camphor                            | 207     |
| Bis(2-methoxyethyl)ether                   | 160     | 1,3-Butanediol                     | 207.5   |
| Isopentyl propionate                       | 160.2   | 1,2,3,4-Tetrahydro-naphthalene     | 207.6   |
| 2-Heptanol                                 | 160.4   | $\gamma$ -Valerolactone            | 207–208 |
| Pentachloroethane                          | 160.5   | <i>o</i> -Chloroaniline            | 208.8   |
| 2-Furaldehyde                              | 161.8   | Nitrobenzene                       | 210.8   |
| 2,6-Dimethyl-4-heptanone                   | 168.1   | Ethyl benzoate                     | 212.4   |
| 4-Hydroxy-4-methyl-2-pentanone             | 169.2   | 3,5,5-Trimethylcyclohex-2-en-1-one | 215.2   |
| 2-Furanmethanol                            | 170.0   | Naphthalene                        | 217.7   |
| Ethoxybenzene                              | 170     | 2-(2-Ethoxyethoxy)ethyl acetate    | 218.5   |
| 2-Butoxyethanol                            | 170.2   | Acetamide                          | 221.2   |
| Diisopentyl ether                          | 173.4   | Methyl salicylate                  | 223.0   |
| Decane                                     | 174.2   | Diethyl maleate                    | 225.3   |
| 1,3-Dichloro-2-propanol                    | 174.3   | 1,4-Butanediol                     | 230     |
| Cyclohexyl acetate                         | 174–175 | Propyl benzoate                    | 231.2   |
| 1-Heptanol                                 | 175.8   | 1-Decanol                          | 230.2   |
| Furfuryl acetate                           | 175–177 | Phenylacetone nitrile              | 233.5   |

| Name                              | BP, °C  | Name                            | BP, °C  |
|-----------------------------------|---------|---------------------------------|---------|
| 2-Phenoxyethanol                  | 240     | Isopentyl salicylate            | 277–278 |
| Bis(2-hydroxyethyl) ether         | 245     | 1-Bromonaphthalene              | 281.1   |
| Dibutyl oxalate                   | 245.5   | Dimethyl <i>o</i> -phthalate    | 283.7   |
| Butyl benzoate                    | 250     | 2,2'-(Ethylenedioxy)-bisethanol | 285     |
| 1,2,3-Propanetriol triacetate     | 258–259 | Glycerol                        | 290     |
| 1-Chloronaphthalene               | 259.3   | Diethyl <i>o</i> -phthalate     | 295     |
| Isopentyl benzoate                | 262     | Benzyl benzoate                 | 323.5   |
| <i>trans</i> -Ethyl cinnamate     | 271.0   | Dibutyl <i>o</i> -phthalate     | 340.0   |
| Bis[2-(methoxyethoxy)-ethyl]ether | 275.3   | Dibutyl decanedioate            | 344–345 |
| 1-Methoxy-2-nitrobenzene          | 277     |                                 |         |

**TABLE 11.9** Molecular Elevation of the Boiling Point*Ebullioscopic constants.*

Molecular weights can be determined with the relation:

$$M = E_b \frac{1000 w_2}{w_1 \Delta T_b}$$

where  $\Delta T_b$  is the elevation of the boiling point brought about by the addition of  $w_2$  grams of solute to  $w_1$  grams of solvent and  $E_b$  is the ebullioscopic constant. In the column headed "Barometric correction" is the number of degrees for each millimeter of difference between the barometric reading and 760 mmHg to be subtracted from  $E_b$  if the pressure is lower, or added if higher, than 760 mm. In general, the effect is within experimental error if the pressure is within 10 mm of 760 mm.

The ebullioscopic constant, a characteristic property of the solvent, may be calculated from the relation:

$$E_b = \frac{RT_b^2 M}{\Delta_{vap} H}$$

where  $R$  is the molar gas constant,  $M$  is the molar mass of the solvent, and  $\Delta_{vap} H$  the molar enthalpy (heat) of vaporization of the solvent.

| Compound              | Barometric correction | $E_b$ ,<br>°C kg · mol <sup>-1</sup> |

11.4.1 McReynolds' Constants

The *Kovats retention indices* (R.I.) indicate where compounds will appear on a chromatogram with respect to unbranched alkanes injected with the sample. By definition, the R.I. for pentane is 500, for hexane is 600, for heptane is 700, and so on, regardless of the column used or the operating conditions, although the exact conditions and column must be specified, such as liquid loading, particular support used, and any pretreatment. For example, suppose that on a 20% squalane column at 100°C, the retention times for hexane, benzene, and octane are found to be 15, 16, and 25 min, respectively. On a graph of  $\ln t'_R$  (napierian logarithm of the adjusted retention time) of the alkanes versus their retention indices, a R.I. of 653 for benzene is read off the graph. The number 653 for benzene (see last line of Table 11.13 in the column headed “1” under “Reference compounds”) means that it elutes halfway between hexane and heptane on a logarithmic time scale. If the experiment is repeated with a dinonyl phthalate column, the R.I. for benzene is found to be 736 (lying between heptane and octane), which implies that dinonyl phthalate will retard benzene slightly more than squalane will; that is, dinonyl phthalate is slightly more polar than squalane by  $\Delta I = 83$  units (the entry in Table 11.13 for dinonyl phthalate in the column headed “1” under “Reference compounds”). The difference gives a measure of solute-solvent interaction due to all intermolecular forces other than London dispersion forces. The latter are the principal solute-solvent effects with squalane.

TABLE 11.14 Characteristics of Selected Supercritical Fluids

| Fluid                  | Critical<br>temperature, K (°C) | Critical<br>pressure, atm (psi) |
|------------------------|---------------------------------|---------------------------------|
| Ammonia                | 406 (133)                       | 111.3 (1636)                    |
| Argon                  | 151 (– 122)                     | 48.1 (707)                      |
| Benzene                | 562 (289)                       | 48.3 (710)                      |
| Butane                 | 425 (125)                       | 37.5 (551)                      |
| Carbon dioxide         | 304 (31)                        | 72.8 (1070)                     |
| Carbon disulfide       | 552 (279)                       | 78.0 (1147)                     |
| Chlorotrifluoromethane | 379 (106)                       | 40 (588)                        |
| 2,2-Dimethylpropane    | 434 (161)                       | 31.6 (464)                      |
| Ethane                 | 305 (32)                        | 48.2 (706)                      |
| Fluoromethane          | 318 (45)                        | 58.0 (853)                      |
| Heptane                | 540 (267)                       | 27.0 (397)                      |
| Hexane                 | 507 (234)                       | 29.3 (431)                      |
| Hydrogen sulfide       | 373 (100)                       | 88.2 (1296)                     |
| Krypton                | 209 (– 64)                      | 54.3 (798)                      |
| Methane                | 191 (– 82)                      | 45.4 (667)                      |
| Methanol               | 513 (240)                       | 79.9 (1175)                     |
| 2-Methylpropane        | 408 (65)                        | 36.0 (529)                      |
| Nitrogen               | 126 (– 147)                     | 33.5 (492)                      |
| Nitrogen(I) oxide      | 310 (37)                        | 71.5 (1051)                     |
| Pentane                | 470 (197)                       | 33.3 (490)                      |
| Propane                | 470 (197)                       | 41.9 (616)                      |
| Sulfur dioxide         | 431 (158)                       | 77.8 (1144)                     |
| Sulfur hexafluoride    | 319 (46)                        | 37.1 (545)                      |
| Trichloromethane       | 536 (263)                       | 54.9 (807)                      |
| Trifluoromethane       | 299 (26)                        | 47.7 (701)                      |
| Water                  | 647 (374)                       | 217.6 (3199)                    |
| Xenon                  | 290 (17)                        | 57.6 (847)                      |

Now the overall effects due to hydrogen bonding, dipole moment, acid-base properties, and molecular configuration can be expressed as

$$\sum \Delta I = ax' + by' + cz' + du' + es'$$

where  $x' = \Delta I$  for benzene (the column headed "1" in Table 11.13, intermolecular forces typical of aromatics and olefins),  $y' = \Delta I$  for 1-butanol (the column headed "2" in Table 11.13, electron attraction typical of alcohols, nitriles, acids, and nitro and alkyl monochlorides, dichlorides and trichlorides),  $z' = \Delta I$  for 2-pentanone (the column headed "3" in Table 11.13, electron repulsion typical of ketones, ethers, aldehydes, esters, epoxides, and dimethylamino derivatives),  $u' = \Delta I$  for 1-nitropropane (the column headed "4" in Table 11.13, typical of nitro and nitrile derivatives), and  $s' = \Delta I$  for pyridine (or dioxane) (the column headed "5" in Table 11.13).

## 11.4.2 Chromatographic Behavior of Solutes

**11.4.2.1 Retention Behavior.** On a chromatogram the distance on the time axis from the point of sample injection to the peak of an eluted component is called the *uncorrected retention time*  $t_R$ . The corresponding retention volume is the product of retention time and flow rate, expressed as volume of mobile phase per unit time:

$$V_R = t_R F_c$$

The *average linear velocity*  $u$  of the mobile phase in terms of the column length  $L$  and the average linear velocity of eluent  $t_M$  (which is measured by the transit time of a nonretained solute) is

$$u = \frac{L}{t_M}$$

The *adjusted retention time*  $t'_R$  is given by

$$t'_R = t_R - t_M$$

When the mobile phase is a gas, a *compressibility factor*  $j$  must be applied to the adjusted retention volume to give the *net retention volume*:

$$V_N = jV_R$$

The compressibility factor is expressed by

$$j = \frac{3[(P_i/P_o)^2 - 1]}{2[(P_i/P_o)^3 - 1]}$$

where  $P_i$  is the carrier gas pressure at the column inlet and  $P_o$  that at the outlet.

**11.4.2.2 Partition Ratio.** The partition ratio is the additional time a solute band takes to elute, as compared with an unretained solute (for which  $k' = 0$ ), divided by the elution time of an unretained band:

$$k' = \frac{t_R - t_M}{t_M} = \frac{V_R - V_M}{V_M}$$

Retention time may be expressed as

$$t_R = t_M(1 + k') = \frac{L}{u}(1 + k')$$

**11.4.2.3 Relative Retention.** The relative retention  $\alpha$  of two solutes, where solute 1 elutes before solute 2, is given variously by

$$\alpha = \frac{k'_2}{k'_1} = \frac{V'_{R,2}}{V'_{R,1}} = \frac{t'_{R,2}}{t'_{R,1}}$$

The relative retention is dependent on (1) the nature of the stationary and mobile phases and (2) the column operating temperature.

**11.4.2.4 Column Efficiency.** Under ideal conditions the profile of a solute band resembles that given by a Gaussian distribution curve (Fig. 11.1). The efficiency of a chromatographic system is expressed by the effective plate number  $N_{\text{eff}}$ , defined from the chromatogram of a single band,

$$N_{\text{eff}} = \frac{L}{H} = 16 \left( \frac{t'_R}{W_b} \right)^2 = 5.54 \left( \frac{t'_R}{W_{1/2}} \right)^2$$

where  $L$  is the column length,  $H$  is the plate height,  $t'_R$  is the adjusted time for elution of the band center,  $W_b$  is the width at the base of the peak ( $W_b = 4\sigma$ ) as determined from the intersections of tangents to the inflection points with the baseline, and  $W_{1/2}$  is the width at half the peak height. Column efficiency, when expressed as the number of theoretical plates  $N_{\text{theor}}$  uses the uncorrected retention time in the foregoing expression. The two column efficiencies are related by

$$N_{\text{eff}} = N_{\text{theor}} \left( \frac{k'}{k' + 1} \right)^2$$

**11.4.2.5 Band Asymmetry.** The peak asymmetry factor  $AF$  is often defined as the ratio of peak half-widths at 10% of peak height, that is, the ratio  $b/a$ , as shown in Fig. 11.2. When the asymmetry ratio lies outside the range 0.95–1.15 for a peak of  $k' = 2$ , the effective plate number should be calculated from the expression

$$N = \frac{41.7(t'_R/W_{0.1})}{(a/b) + 1.25}$$

**11.4.2.6 Resolution.** The degree of separation or resolution,  $R_s$ , of two adjacent peaks is defined as the distance between band peaks (or centers) divided by the average bandwidth using  $W_b$ , as shown in Fig. 11.3.

$$R_s = \frac{t_{R,2} - t_{R,1}}{0.5(W_2 + W_1)}$$

FIGURE 11.1 Profile of a solute band.

FIGURE 11.2 Band asymmetry.

For reasonable quantitative accuracy, peak maxima must be at least  $4\sigma$  apart. If so, then  $R_s = 1.0$ , which corresponds approximately to a 3% overlap of peak areas. A value of  $R_s = 1.5$  (for  $6\sigma$ ) represents essentially complete resolution with only 0.2% overlap of peak areas. These criteria pertain to roughly equal solute concentrations.

The fundamental resolution equation incorporates the terms involving the thermodynamics and kinetics of the chromatographic system:

$$R_s = \frac{1}{4} \left( \frac{\alpha - 1}{\alpha} \right) \left( \frac{k'}{1 + k'} \right) \left( \frac{L}{H} \right)^{1/2}$$

Three separate factors affect resolution: (1) a column selectivity factor that varies with  $\alpha$ , (2) a capacity factor that varies with  $k'$  (taken usually as  $k_2$ ), and (3) an efficiency factor that depends on the theoretical plate number.

FIGURE 11.3 Definition of resolution.

**11.4.2.7 Time of Analysis.** The retention time required to perform a separation is given by

$$t_R = 16Rs^2 \left( \frac{\alpha}{\alpha - 1} \right)^2 \left[ \frac{(1 + k')^3}{(k')^2} \right] \left( \frac{H}{u} \right)$$

Now  $t_R$  is a minimum when  $k' = 2$ , that is, when  $t_R = 3t_M$ . There is little increase in analysis time when  $k'$  lies between 1 and 10. A twofold increase in the mobile-phase velocity roughly halves the analysis time (actually it is the ratio  $H/u$  which influences the analysis time). The ratio  $H/u$  can be obtained from the experimental plate height/velocity graph.

**11.4.2.8 High-Performance Liquid Chromatography.** Typical performances for various experimental conditions are given in Table 11.15. The data assume these reduced parameters:  $h = 3$ ,  $v = 4.5$ . The reduced plate height is

$$h = \frac{H}{d_p} = \frac{L}{Nd_p}$$

The reduced velocity of the eluent is

$$v = \frac{ud_p}{D_M} = \frac{Ld_p}{t_M D_M}$$

In these expressions,  $d_p$  is the particle diameter of the stationary phase that constitutes one plate height.  $D_M$  is the diffusion coefficient of the solute in the mobile phase.

**TABLE 11.15** Typical Performances in HPLC for Various Conditions

| Performances |           | Column parameters |                       |                 |
|--------------|-----------|-------------------|-----------------------|-----------------|
| $N$          | $t_M$ , s | $L$ , cm          | $d_p$ , $\mu\text{m}$ | $P$ , atm (psi) |
| 2 500        | 30        | 2.3               | 3                     | 18.4 (270)      |
| 2 500        | 30        | 3.7               | 5                     | 18.4 (270)      |
| 2 500        | 30        | 7.5               | 10                    | 18.4 (270)      |
| 5 000        | 30        | 4.5               | 3                     | 74 (1088)       |
| 5 000        | 30        | 7.5               | 5                     | 74 (1088)       |
| 5 000        | 30        | 15.0              | 10                    | 74 (1088)       |
| 10 000       | 30        | 9.0               | 3                     | 300 (4410)      |
| 10 000       | 30        | 15.0              | 5                     | 300 (4410)      |
| 10 000       | 30        | 30.0              | 10                    | 300 (4410)      |
| 10 000       | 30        | 9.0               | 3                     | 300 (4410)      |
| 10 000       | 60        | 9.0               | 3                     | 150 (2200)      |
| 10 000       | 90        | 9.0               | 3                     | 100 (1470)      |
| 15 000       | 90        | 2.3               | 3                     | 223 (3275)      |
| 15 000       | 120       | 2.3               | 3                     | 167 (2459)      |
| 11 100       | 30        | 10.0              | 3                     | 369 (5420)      |
| 11 100       | 37        | 10.0              | 3                     | 300 (4410)      |
| 11 100       | 101       | 10.0              | 3                     | 100 (1470)      |
| 27 800       | 231       | 25.0              | 3                     | 300 (4410)      |

Assumed reduced parameters:  $h = 3$ ,  $v = 4.5$ . These are optimum values from a graph of reduced plate height versus reduced linear velocity of the mobile phase.

### 11.4.3 Ion-Exchange (Normal Pressure, Columnar)

Ion-exchange methods are based essentially on a reversible exchange of ions between an external liquid phase and an ionic solid phase. The solid phase consists of a polymeric matrix, insoluble, but permeable, which contains fixed charge groups and mobile counter ions of opposite charge. These counter ions can be exchanged for other ions in the external liquid phase. Enrichment of one or several of the components is obtained if selective exchange forces are operative. The method is limited to substances at least partially in ionized form.

**11.4.3.1 Chemical Structure of Ion-Exchange Resins.** An ion-exchange resin usually consists of polystyrene copolymerized with divinylbenzene to build up an inert three-dimensional, cross-linked matrix of hydrocarbon chains. Protruding from the polymer chains are the ion-exchange sites distributed statistically throughout the entire resin particle. The ionic sites are balanced by an equivalent number of mobile counter ions. The type and strength of the exchanger is determined by these active groups. Ion-exchangers are designated anionic or cationic, according to whether they have an affinity for negative or positive counter ions. Each main group is further subdivided into strongly or weakly ionized groups. A selection of commercially available ion-exchange resins is given in Table 11.16.

The cross-linking of a polystyrene resin is expressed as the proportion by weight percent of divinylbenzene in the reaction mixture; for example, “×8” for 8 percent cross-linking. As the percentage is increased, the ionic groups come into effectively closer proximity, resulting in increased selectivity. Intermediate cross-linking, in the range of 4 to 8 percent, is usually used. An increase in cross-linking decreases the diffusion rate in the resin particles; the diffusion rate is the rate-controlling step in column operations. Decreasing the particle size reduces the time required for attaining equilibrium, but at the same time decreases the flow rate until it is prohibitively slow unless pressure is applied.

In most inorganic chromatography, resins of 100 to 200 mesh size are suitable; difficult separations may require 200 to 400 mesh resins. A flow rate of  $1 \text{ mL} \cdot \text{cm}^{-2} \cdot \text{min}^{-1}$  is often satisfactory. With HPLC columns, the flow rate in long columns of fine adsorbent can be increased by applying pressure.

**11.4.3.1.1 Macroreticular Resins.** Macroreticular resins are an agglomerate of randomly packed microspheres which extend through the agglomerate in a continuous non-gel pore structure. The channels throughout the rigid pore structure render the bead centers accessible even in non-aqueous solvents, in which microreticular resins do not swell sufficiently. Because of their high porosity and large pore diameters, these resins can handle large organic molecules.

**11.4.3.1.2 Microreticular Resins.** Microreticular resins, by contrast, are elastic gels that, in the dry state, avidly absorb water and other polar solvents in which they are immersed. While taking up solvent, the gel structure expands until the retractile stresses of the distended polymer network balance the osmotic effect. In nonpolar solvents, little or no swelling occurs and diffusion is impaired.

**11.4.3.1.3 Ion-Exchange Membranes.** Ion-exchange membranes are extremely flexible, strong membranes, composed of analytical grade ion-exchange resin beads (90%) permanently enmeshed in a poly(tetrafluoroethylene) membrane (10%). The membranes offer an alternative to column and batch methods, and can be used in many of the same applications as traditional ion exchange resins. Three ion-exchange resin types have been incorporated into membranes: AG 1-X8, AG 50W-X8, and Chelex 100.

### 11.4.3.2 Functional Groups

*Sulfonate exchangers* contain the group  $-\text{SO}_3^-$ , which is strongly acidic and completely dissociated whether in the H form or the cation form. These exchangers are used for cation exchange.

**TABLE 11.16** Guide to Ion-Exchange Resins

Dowex is the trade name of Dow resins; X (followed by a numeral) is percent cross-linked. Mesh size (dry) are available in the range 50 to 100, 100 to 200, 200 to 400, and sometimes minus 400.

S-DVB is the acronym for styrene-divinylbenzene.

MP is the acronym for macroporous resin. Mesh size (dry) is available in the range 20 to 50, 100 to 200, and 200 to 400.

Bio-Rex is the trade name for certain resins sold by Bio-Rad Laboratories.

Amberlite and Duolite are trade names of Rohm & Haas resins.

| Resin type and nominal percent cross-linkage                                    | Minimum wet capacity, mequiv $\cdot$ mL <sup>-1</sup> | Density (nominal), g $\cdot$ mL <sup>-1</sup> | Comments                                                                                                                                                                                    |

| Amberlite IR-122                                                            | 2.1                                                   | 1.32                                          | 10% styrene-DVB type; high physical stability and high capacity.                                                                                                                                                                                                          |
| Weakly acidic cation exchangers—gel type—carboxylic acid functionality      |                                                       |                                               |                                                                                                                                                                                                                                                                           |
| Duolite C-433                                                               | 4.5                                                   | 1.19                                          | Acrylic-DVB type; very high capacity. Used for metals removal and neutralization of alkaline solutions.                                                                                                                                                                   |
| Bio-Rex 70                                                                  | 2.4                                                   | 0.70                                          | Weakly acidic cation exchanger with carboxylate groups on a macroreticular acrylic matrix for separation and fractionation of proteins, peptides, enzymes, and amines, particularly high molecular weight solutes. Does not denature proteins as do styrene-based resins. |

**TABLE 11.16** Guide to Ion-Exchange Resins (*Continued*)

| Resin type and nominal percent cross-linkage                                         | Minimum wet capacity, mequiv · mL <sup>-1</sup> | Density (nominal), g · mL <sup>-1</sup> | Comments                                                                                                                                               |
|--------------------------------------------------------------------------------------|-------------------------------------------------|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| Selective ion exchange resins                                                        |                                                 |                                         |                                                                                                                                                        |
| Duolite GT-73                                                                        | 1.3                                             | 1.30                                    | Removal of Ag, Cd, Cu, Hg, and Pb.                                                                                                                     |
| Amberlite IRA-743A                                                                   | 0.6                                             | 1.05                                    | Boron specific ion exchange resin.                                                                                                                     |
| Amberlite IRC-718                                                                    | 1.0                                             | 1.14                                    | Removal of transition metals.                                                                                                                          |
| Chelex® 100                                                                          | 0.4                                             | 0.65                                    | Weakly acidic chelating resin with S-DVB matrix for heavy metal concentration.                                                                         |
| Anion exchanger—macroreticular type—strongly basic—quaternary ammonium functionality |                                                 |                                         |                                                                                                                                                        |
| Amberlite IRA-910                                                                    | 1.1                                             | 1.09                                    | Dimethylethanolamine styrene-DVB type which offers slightly less silica removal than Amberlite IRA resin, but offers improved regeneration efficiency. |
| Amberlite IRA-938                                                                    | 0.5                                             | 1.20                                    | Pore size distribution between 2500 and 23 000 nm; suitable for removal of high molecular weight organic materials.                                    |
| Amberlite IRA-958                                                                    | 0.8                                             |                                         | Acrylic-DVB; resistant to organic fouling.                                                                                                             |
| AG MP-1                                                                              | 1.0                                             | 0.70                                    | Strongly basic macroporous anion exchanger with S-DVB matrix for separation of some enzymes, radioactive anions, and other applications.               |
| Cation exchange resin—macroreticular type—sulfonic acid functionality                |                                                 |                                         |                                                                                                                                                        |
| Amberlite 200                                                                        | 1.7                                             | 1.26                                    | Styrene-DVB with 20% DVB by weight; superior physical stability and greater resistance to oxidation by factor of three over comparable gel type resin. |
| AG MP-50                                                                             | 1.5                                             | 0.80                                    | Strongly acidic macroporous cation exchanger with S-DVB matrix for separation of radioactive cations and other applications.                           |
| Weak cation exchanger—macroreticular type—carboxylic acid or phenolic functionality  |                                                 |                                         |                                                                                                                                                        |
| Amberlite DP-1                                                                       | 2.5                                             | 1.17                                    | Methacrylic acid-DVB; high resin capacity. Use pH >5.                                                                                                  |
| Amberlite IRC-50                                                                     | 3.5                                             | 1.25                                    | Methacrylic acid-DVB. Selectivity adsorbs organic gases such as antibiotics, alkaloids, peptides, and amino acids. Use pH >5.                          |
| Duolite C-464                                                                        | 3.0                                             | 1.13                                    | Polyacrylic resin with high capacity and outstanding resistance to osmotic shock.                                                                      |

**TABLE 11.16** Guide to Ion-Exchange Resins (*Continued*)

| Resin type and nominal percent cross-linkage                                                             | Minimum wet capacity, mequiv · mL <sup>-1</sup> | Density (nominal), g · mL <sup>-1</sup> | Comments                                                                                                                                                                                     |
|----------------------------------------------------------------------------------------------------------|-------------------------------------------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Weak cation exchanger—macroreticular type—carboxylic acid or phenolic functionality ( <i>continued</i> ) |                                                 |                                         |                                                                                                                                                                                              |
| Duolite A-7                                                                                              | 2.2                                             | 1.12                                    | Phenolic type resin. High porosity and hydrophilic matrix. pH range is 0 to 6.                                                                                                               |
| Duolite A-368                                                                                            | 1.7                                             | 1.04                                    | Styrene-DVB; pH range is 0 to 9.                                                                                                                                                             |
| Amberlite IRA-35                                                                                         | 1.1                                             |                                         | Acrylic-DVB; pH range is 0 to 9.                                                                                                                                                             |
| Amberlite IRA-93                                                                                         | 1.3                                             | 1.04                                    | Styrene-DVB; pH range is 0 to 9. Excellent resistance to oxidation and organic fouling.                                                                                                      |
| Liquid amines                                                                                            |                                                 |                                         |                                                                                                                                                                                              |
| Amberlite LA-1                                                                                           |                                                 |                                         | A secondary amine containing two highly branched aliphatic chains of M.W. 351 to 393. Solubility is 15 to 20 mg/mL in water. Used as 5 to 40% solutions in hydrocarbons.                     |
| Amberlite LA-2                                                                                           |                                                 |                                         | A secondary amine of M.W. 353 to 395. Insoluble in water.                                                                                                                                    |
| Microcrystalline exchanger                                                                               |                                                 |                                         |                                                                                                                                                                                              |
| AMP-1                                                                                                    | 4.0                                             |                                         | Microcrystalline ammonium molybdo-phosphate with cation exchange capacity of 1.2 mequiv/g. Selectively adsorbs larger alkali metal ions from smaller alkali metal ions, particularly cesium. |
| Ion retardation resin                                                                                    |                                                 |                                         |                                                                                                                                                                                              |

Selectively retards ionic substances.                     |

**Source:** J. A. Dean, ed., *Analytical Chemistry Handbook*, McGraw-Hill, New York, 1995.

*Carboxylate exchangers* contain —COOH groups which have weak acidic properties and will only function as cation exchangers when the pH is sufficiently high (pH > 6) to permit complete dissociation of the —COOH site. Outside this range the ion exchanger can be used only at the cost of reduced capacity.

*Quaternary ammonium exchangers* contain —R<sub>4</sub>N<sup>+</sup> groups which are strongly basic and completely dissociated in the OH form and the anion form.

*Tertiary amine exchangers* possess —R<sub>3</sub>NH<sub>2</sub> groups which have exchanging properties only in an acidic medium when a proton is bound to the nitrogen atom.

*Aminodiacetate exchangers* have the —N(CH<sub>2</sub>COOH)<sub>2</sub> group which has an unusually high preference for copper, iron, and other heavy metal cations and, to a lesser extent, for alkaline earth

cations. The resin selectivity for divalent over monovalent ions is approximately 5000 to 1. The resin functions as a chelating resin at pH 4 and above. At very low pH, the resin acts as an anion exchanger. This exchanger is the column packing often used for ligand exchange.

**11.4.3.3 Ion-Exchange Equilibrium.** Retention differences among cations with an anion exchanger, or among anions with a cation exchanger, are governed by the physical properties of the solvated ions. The stationary phase will show these preferences:

1. The ion of higher charge.
2. The ion with the smaller solvated radius. Energy is needed to strip away the solvation shell surrounding ions with large hydrated radii, even though their crystallographic ionic radii may be less than the average pore opening in the resin matrix.
3. The ion that has the greater polarizability (which determines the Van der Waals' attraction).

To accomplish any separation of two cations (or two anions) of the same net charge, the stationary phase must show a preference for one more than the other. No variation in the eluant concentration will improve the separation. However, if the exchange involves ions of different net charges, the separation factor does depend on the eluant concentration. The more dilute the counterion concentration in the eluant, the more selective the exchange becomes for polyvalent ions.

In the case of an ionized resin, initially in the H-form and in contact with a solution containing  $K^+$  ions, an equilibrium exists:

which is characterized by the selectivity coefficient,  $k_{K/H}$ :

$$k_{K/H} = \frac{[K^+]_r [H^+]}{[H^+]_r [K^+]}$$

where the subscript  $r$  refers to the resin phase. Table 11.17 contains selectivity coefficients for cations and Table 11.18 for anions. Relative selectivities are of limited use for the prediction of the columnar

exchange behavior of a cation because they do not take account of the influence of the aqueous phase. More specific information about the behavior to be expected from a cation in a column elution experiment is given by the equilibrium distribution coefficient  $K_d$ .

The partitioning of the potassium ion between the resin and solution phases is described by the concentration distribution ratio,  $D_c$ :

$$(D_c)_K = \frac{[K^+]_r}{[K^+]}$$

Combining the equations for the selectivity coefficient and for  $D_c$ :

$$(D_c)_K = k_{K/H} \frac{[H^+]_r}{[H^+]}$$

The foregoing equation reveals that essentially the concentration distribution ratio for trace concentrations of an exchanging ion is independent of the respective solution of that ion and that the uptake of each trace ion by the resin is directly proportional to its solution concentration. However, the

concentration distribution ratios are inversely proportional to the solution concentration of the resin counterion.

To accomplish any separation of two cations (or two anions), one of these ions must be taken up by the resin in distinct preference to the other. This preference is expressed by the separation factor (or relative retention),  $\alpha_{K/Na}$ , using  $K^+$  and  $Na^+$  as the example:

$$\alpha_{K/Na} = \frac{(D_c)_K}{(D_c)_{Na}} = \frac{k_{K/H}}{k_{Na/H}} = K_{K/Na}$$

The more  $\alpha$  deviates from unity for a given pair of ions, the easier it will be to separate them. If the selectivity coefficient is unfavorable for the separation of two ions of the same charge, no variation in the concentration of  $H^+$  (the eluant) will improve the separation.

The situation is entirely different if the exchange involves ions of different net charges. Now the separation factor does depend on the eluant concentration. For example, the more dilute the counterion concentration in the eluant, the more selective the exchange becomes for the ion of higher charge.

In practice, it is more convenient to predict the behavior of an ion, for any chosen set of conditions, by employing a much simpler distribution coefficient,  $D_g$ , which is defined as the concentration of a solute in the resin phase divided by its concentration in the liquid phase, or:

$$D_g = \frac{\text{concentration of solute, resin phase}}{\text{concentration of solute, liquid phase}}$$

$$D_g = \frac{\% \text{ solute within exchanger}}{\% \text{ solute within solution}} \times \frac{\text{volume of solution}}{\text{mass of exchanger}}$$

$D_g$  remains constant over a wide range of resin to liquid ratios. In a relatively short time, by simple equilibration of small known amounts of resin and solution followed by analysis of the phases, the distribution of solutes may be followed under many different sets of experimental conditions. Variables requiring investigation include the capacity and percent cross-linkage of resin, the type of resin itself, the temperature, and the concentration and pH of electrolyte in the equilibrating solution.

By comparing the ratio of the distribution coefficients for a pair of ions, a separation factor (or relative retention) is obtained for a specific experimental condition.

Instead of using  $D_g$ , separation data may be expressed in terms of a volume distribution coefficient  $D_v$ , which is defined as the amount of solution in the exchanger per cubic centimeter of resin bed divided by the amount per cubic centimeter in the liquid phase. The relation between  $D_g$  and  $D_v$  is given by:

$$D_v = D_g \rho$$

where  $\rho$  is the bed density of a column expressed in the units of mass of dry resin per cubic centimeter of column. The bed density can be determined by adding a known weight of dry resin to a graduated cylinder containing the eluting solution. After the resin has swelled to its maximum, a direct reading of the settled volume of resin is recorded.

Intelligent inspection of the relevant distribution coefficients will show whether a separation is feasible and what the most favorable eluant concentration is likely to be. In the columnar mode, an ion, even if not eluted, may move down the column a considerable distance and with the next eluant may appear in the eluate much earlier than indicated by the coefficient in the first eluant alone. A

distribution coefficient value of 12 or lower is required to elute an ion completely from a column containing about 10 g of dry resin using 250 to 300 mL of eluant. A larger volume of eluant is required only when exceptionally strong tailing occurs. Ions may be eluted completely by 300 to 400 mL of eluant from a column of 10 g of dry resin at  $D_g$  values of around 20. The first traces of an element will appear in the eluate at around 300 mL when its  $D_g$  value is about 50 to 60.

*Example* Shaking 50 mL of 0.001  $M$  cesium salt solution with 1.0 g of a strong cation exchanger in the H-form (with a capacity of 3.0 mequiv  $\cdot$  g $^{-1}$ ) removes the following amount of cesium. The selectivity coefficient,  $k_{Cs/H}$ , is 2.56, thus:

$$\frac{[Cs^+]_r[H^+]}{[Cs^+][H^+]_r} = 2.56$$

The maximum amount of cesium which can enter the resin is 50 mL  $\times$  0.001  $M$  = 0.050 equiv. The minimum value of  $[H^+]_r$  = 3.00 – 0.05 = 2.95 mequiv, and the maximum value, assuming complete exchange of cesium ion for hydrogen ion, is 0.001  $M$ . The minimum value of the distribution ratio is:

$$(D_c)_{Cs} = \frac{[Cs^+]_r}{[Cs^+]} = \frac{(2.56)(2.95)}{0.001} = 7550$$

$$\frac{\text{Amount of Cs, resin phase}}{\text{Amount of Cs, solution phase}} = \frac{(7550)(1.0 \text{ g})}{50 \text{ mL}} = 151$$

Thus, at equilibrium the 1.0 g of resin removed is:

$$\frac{100\% - x}{x} = 151$$

with all but 0.66% of cesium ions from solution. If the amount of resin were increased to 2.0 g, the amount of cesium remaining in solution would decrease to 0.33%, half the former value. However, if the depleted solution were decanted and placed in contact with 1 g of fresh resin, the amount of cesium remaining in solution would decrease to 0.004%. Two batch equilibrations would effectively remove the cesium from the solution.

11.5 GRAVIMETRIC ANALYSIS

TABLE 11.19 Gravimetric Factors

In the following table the elements are arranged in alphabetical order.  
Example: To convert a given weight of  $\text{Al}_2\text{O}_3$  to its equivalent of Al, multiply by the factor at the right, 0.52926; similarly to convert Al to  $\text{Al}_2\text{O}_3$ , multiply by the factor at the left, 1.8894.

| Factor                           |                                                                                                                                | Factor   |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------|----------|
| <b>ALUMINUM</b>                  |                                                                                                                                |          |
| <b>Al = 26.9815</b>              |                                                                                                                                |          |

**TABLE 11.20** Elements Precipitated by General Analytical Reagents

This table includes the more common reagents used in gravimetric determinations. The lists of elements precipitated are not in all cases exhaustive. The usual solvent for a precipitating agent is indicated in parentheses after its name or formula. When the symbol of an element or radical is italicized, the element may be quantitatively determined by the use of the reagent in question.

| Reagent                                                               | Conditions                                                                                                                            | Substances precipitated                                                                                                    |
|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Ammonia, $NH_3$ (aqueous)                                             | After removal of acid sulfide group.                                                                                                  | <i>Al, Au, Be, Co, Cr, Cu, Fe, Ga, In, Ir, La, Nb, Ni, Os, P, Pb, rare earths, Sc, Si, Sn, Ta, Th, Ti, U, V, Y, Zn, Zr</i> |
| Ammonium polysulfide, $(NH_4)_2S_x$ (aqueous)                         | After removal of acid sulfide and $(NH_4)_2S$ groups.                                                                                 | Co, Mn, Ni, Si, Ti, V, W, Zn                                                                                               |
| Anthranilic acid, $NH_2C_6H_4COOH$ (aqueous)                          | 1% aqueous solution (pH 6); Cu separated from others at pH 2.9.                                                                       | Ag, <i>Cd, Co, Cu, Fe, Hg, Mn, Ni, Pb, Zn</i>                                                                              |
| $\alpha$ -Benzoin oxime, $C_6H_5CHOHC(=NOH)C_6H_5$ (1–2% alcohol)     | (a) Strongly acid medium.                                                                                                             | (a) <i>Cr(VI), Mo(VI), Nb, Pd(II), Ta(V), V(V), W(VI)</i>                                                                  |
| Benzidine, $H_2NC_6H_4C_6H_4NH_2$ (alcohol), 0.1M HCl                 | (b) Ammoniacal tartrate medium.                                                                                                       | (b) Above list                                                                                                             |
| <i>N</i> -Benzoylphenylhydroxylamine, $C_6H_5CO(C_6H_5)NOH$ (aqueous) | Similar to cupferron ( <i>q.v.</i> ). Cu, Fe(III), and Al complexes can be weighed as such; Ti compound must be ignited to the oxide. | <i>Cd, Fe(III), IO_3^-, PO_4^{3-}, SO_4^{2-}, W(VI)</i><br>See Cupferron                                                   |
| Cinchonine, $C_{19}H_{21}N_2OH$ , 6M HCl                              |                                                                                                                                       | Ir, Mo, Pt, W                                                                                                              |
| Cupferron, $C_6H_5N(NO)ONH_4$ (aqueous)                               | Group precipitant for several higher-charged metal ions from strongly acid solution. Precipitate ignited to metal oxide.              | <i>Al, Bi, Cu, Fe, Ga, La, Mo, Nb, Pd, rare earths, Sb, Sn, Ta, Th, Ti, Tl, U, V, W, Zr</i>                                |
| 1,2-Cyclohexanedionedioxime                                           | More water soluble than dimethylglyoxime; less subject to coprecipitation with metal chelate.                                         | See Dimethylglyoxime                                                                                                       |

**TABLE 11.24** Porosities of Fritted Glassware

| Porosity     | Nominal maximum pore size, $\mu\text{m}$ | Principal uses                                                                                                             |
|--------------|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Extra coarse | 170–220                                  | Filtration of very coarse materials. Gas dispersion, gas washing, and extractor beds. Support of other filter materials.   |
| Coarse       | 40–60                                    | Filtration of coarse materials. Gas dispersion, gas washing, gas absorption. Mercury filtration. For extraction apparatus. |
| Medium       | 10–15                                    | Filtration of crystalline precipitates. Removal of “floaters” from distilled water.                                        |
| Fine         | 4–5.5                                    | Filtration of fine precipitates. As a mercury valve. In extraction apparatus.                                              |
| Very fine    | 2–2.5                                    | General bacteria filtrations.                                                                                              |
| Ultra fine   | 0.9–1.4                                  | General bacteria filtrations.                                                                                              |

**TABLE 11.25** Tolerances for Analytical Weights

By Alan D. Westland with Fred E. Beamish.

This table gives the individual and group tolerances established by the National Bureau of Standards (Washington, D.C.) for classes M, S, S-1, and P weights. Individual tolerances are “acceptance tolerances” for new weights. Group tolerances are defined by the National Bureau of Standards as follows: “The corrections of individual weights shall be such that no combination of weights that is intended to be used in a weighing shall differ from the sum of the nominal values by more than the amount listed under the group tolerances.”

For class S-1 weights, two-thirds of the weights in a set must be within one-half of the individual tolerances given below. No group tolerances have been specified for class P weights. See *Natl. Bur. Standards Circ.* 547, sec. 1 (1954).

| Denomination | Class M                  |                     | Class S                  |                     | Class S-1, individual tolerance, mg | Class P, individual tolerance, mg |
|--------------|--------------------------|---------------------|--------------------------|---------------------|-------------------------------------|-----------------------------------|
|              | Individual tolerance, mg | Group tolerance, mg | Individual tolerance, mg | Group tolerance, mg |                                     |                                   |
| 100 g        | 0.50                     | None specified      | 0.25                     | None specified      | 1.0                                 | 2.0                               |
| 50 g         | 0.25                     |                     | 0.12                     |                     | 0.60                                | 1.2                               |

TABLE 11.26 Heating Temperatures, Composition of Weighing Forms, and Gravimetric Factors

The minimum temperature required for heating a pure precipitate to constant weight is frequently lower than that commonly recommended in gravimetric procedures. However, the higher temperature is very often still to be preferred in order to ensure that contaminating substances are expelled. The thermal stability ranges of various precipitates as deduced from thermograms are also tabulated. Where a stronger ignition is advisable, the safe upper limit can be ascertained.

Gravimetric factors are based on the 1993 International Atomic Weights. The factor Ag: 0.7526 given in the first line of the table indicates that the weight of precipitate obtained (AgCl) is to be multiplied by 0.7526 to calculate the corresponding weight of silver.

| Element | Thermal stability<br>range, °C | Final heating<br>temperature, °C | Composition of<br>weighing form                                  | Gravimetric factors                                 |

| (HOCH <sub>2</sub> ) <sub>3</sub> CNHH <sub>2</sub>                | 121.137        | Tris(hydroxymethyl)aminomethane is available commercially as a primary standard. Dry at 100–103°C (<110°C). In titrations with a strong acid the equivalence point is at about pH 4.5–5. Equivalent weight is the formula weight. [J. H. Fossum, P. C. Markunas, and J. A. Riddick, <i>Anal. Chem.</i> , <b>23</b> :491 (1951).]                                                                                                                                                               |
| HgO                                                                | 216.59         | Dissolve 100 g pure HgCl <sub>2</sub> in 1 L H <sub>2</sub> O, and add with stirring to 650 mL 1.5 M NaOH. Filter and wash with H <sub>2</sub> O until washings are neutral to phenolphthalein. Dry to constant weight at or below 40°C, and store in a dark bottle. To 0.4 g HgO (≡ 40 mL 0.1N acid) add 10–15 g KBr plus 20–25 mL H <sub>2</sub> O. Stir, excluding CO <sub>2</sub> , until solution is complete. Titrate with acid to pH 5–8. Equivalent weight is one-half formula weight. |
| Na <sub>2</sub> B <sub>4</sub> O <sub>7</sub> · 10H <sub>2</sub> O | 381.372        | Recrystallize reagent-grade salt twice from water at temperatures below 55°C. Wash the crystals with H <sub>2</sub> O, twice with ethanol, and twice with diethyl ether. Let stand in a hygrostat oversaturated NaBr · 2H <sub>2</sub> O or saturated NaCl-sucrose solution. Use methyl red indicator. Equivalent weight is one-half the formula weight.                                                                                                                                       |

**TABLE 11.27** Primary Standards for Aqueous Acid-Base Titrations (*Continued*)

| Standard                                                                 | Formula weight | Preparation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Basic substances for standardizing acidic solutions ( <i>continued</i> ) |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Na <sub>2</sub> CO <sub>3</sub>                                          | 105.989        | Heat reagent-grade material for 1 hr at 255–265°C. Cool in an efficient desiccator. Titrate sample with acid to pH 4–5 (first green tint of bromocresol green), boil the solution to eliminate the carbon dioxide, cool, and again titrate to pH 4–5. Equivalent weight is one-half the formula weight.                                                                                                                                                                                              |
| NaCl                                                                     | 58.45          | Accurately weigh about 6 g NaCl and dissolve in distilled water. Pass the solution through a well-rinsed cation exchange column (Dowex 50W) in the hydrogen form. The equivalent amount of HCl is washed from the column (in 10 column volumes) into a volumetric flask and made up to volume. Equivalent weight is the formula weight.                                                                                                                                                              |
| Acidic substances for standardizing basic solutions                      |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| C <sub>6</sub> H <sub>5</sub> COOH                                       | 122.125        | Pure benzoic acid is available from NIST (National Institute for Science and Technology). Dissolve 0.5 g in 20 mL of neutral ethanol (run a blank), excluding CO <sub>2</sub> , add 20–50 mL, and titrate using phenolphthalein as indicator.                                                                                                                                                                                                                                                        |
| <i>o</i> -C <sub>6</sub> H <sub>4</sub> (COOK)(COOH)                     | 204.22         | Potassium hydrogen <i>o</i> -phthalate is available commercially as primary standard, also from NIST. Dry at <135°C. Dissolve in water, excluding CO <sub>2</sub> , and titrate with phenolphthalein as indicator. For Ba(OH) <sub>2</sub> solution, perform the titration at an elevated temperature to prevent precipitation of Ba phthalate.                                                                                                                                                      |
| KH(IO <sub>3</sub> ) <sub>2</sub>                                        | 389.915        | Potassium hydrogen bis(iodate) is available commercially in a primary standard grade. Dry at 110°C. Dissolve a weighed amount of the salt in water, excluding CO <sub>2</sub> , and titrate to pH 5–8. [I. M. Kolthoff and L. H. van Berk, <i>J. Am. Chem. Soc.</i> , <b>48</b> :2800 (1926)].                                                                                                                                                                                                       |
| NH <sub>2</sub> SO <sub>3</sub> H                                        | 97.09          | Hydrogen amidosulfate (sulfamic acid) acts as a strong acid. Primary standard grade is available commercially. Since it does undergo slow hydrolysis, an acid end point (pH 4 to 6.5) should be chosen unless fresh reagent is available, then the end point can be in the range pH 4 to 9. [W. F. Wagner, J. A. Wuellner, and C. E. Feiler, <i>Anal. Chem.</i> , <b>24</b> :1491 (1952). M. J. Butler, G. F. Smith, and L. F. Audrieth, <i>Ind. Eng. Chem., Anal. Ed.</i> , <b>10</b> :690 (1938)]. |

TABLE 11.28 Titrimetric (Volumetric) Factors

| Acids                                                                                                                                                                                                                                  |                                                                    |          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|----------|
| The following factors are the equivalent of 1 mL of <i>normal acid</i> . Where the normality of the solution being used is other than normal, multiply the factors given in the table below by the normality of the solution employed. |                                                                    |          |
| The equivalents of the esters are based on the results of saponification.                                                                                                                                                              |                                                                    |          |
| The indicators methyl orange and phenolphthalein are indicated by the abbreviations MO and pH, respectively.                                                                                                                           |                                                                    |          |
| Substance                                                                                                                                                                                                                              | Formula                                                            | Grams    |

| Alkali                     |                                                              |          |

The following factors are the equivalent of the milliliter of *normal alkali*. Where the normality of the solution being used is other than normal, multiply the factors given in the table below by the normality of the solution employed.

The equivalents of the esters are based on the results of saponification.

The indicators methyl orange and phenolphthalein are indicated by the abbreviations MO and PH, respectively.

| Substance                 | Formula                                                             | Grams    |

**11.6.2 Titrimetric (Volumetric) Factors for Acid-Base Titrations**

Titrimetric (volumetric) factors for acids and bases are given in Table 11.28. Suitable indicators for acid-base titrations may be found in Tables 8.23 and 8.24.

**11.6.3 Standard Volumetric (Titrimetric) Redox Solutions**

**Alkaline arsenite**, 0.1*N* As(III) to As(V). Dissolve 4.9460 g of primary standard grade  $\text{As}_2\text{O}_3$  in 40 mL of 30% NaOH solution. Dilute with 200 mL of water. Acidify the solution with 6*N* HCl to the acid color of methyl red indicator. Add to this solution 40 g of  $\text{NaHCO}_3$  and dilute to 1 L.

**Ceric sulfate**, 0.1*N* Ce(IV) to Ce(III). Dissolve 63.26 g of cerium(IV) ammonium sulfate dihydrate in 500 mL of 2*N* sulfuric acid. Dilute the solution to 1 L and standardize against the

alkaline arsenite solution as follows: measure, accurately, 30 to 40 mL of arsenite solution into an Erlenmeyer flask and dilute to 150 mL. Add slowly, to prevent excessive frothing, 20 mL of 4*N* sulfuric acid, 2 drops of 0.01*M* osmium tetroxide solution, and 4 drops of 1,10-phenanthroline iron(II) complex indicator. Titrate with the ceric sulfate solution to a faint blue endpoint. Compute the normality of the ceric solution from the normality of the arsenite solution.

**Iron(II) ammonium sulfate hexahydrate**, 0.1*N* Fe(II) to Fe(III). Dissolve 39.2139 g of  $\text{FeSO}_4 \cdot 2(\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$  in 500 mL of 1*N* sulfuric acid and dilute to 1 L. If desired, check against standard dichromate or permanganate solution.

**Iodine**, 0.1*N* (0 to 1–). Dissolve 12.690 g of resublimed iodine in 25 mL of a solution containing 15 g of KI which is free from iodate. After all the solid has dissolved, dilute to 1 L. If desired, check against a standard arsenite or standard thiosulfate solution.

**Potassium bromate**, 0.1*N* (5+ to 1–). Weigh out 2.7833 g of  $\text{KBrO}_3$ , dissolve in water, and dilute to 1 L.

**Potassium dichromate**, 0.1*N* Cr(VI) to Cr(III). Weigh out 4.9030 g of  $\text{K}_2\text{Cr}_2\text{O}_7$  that has been dried at 120°C, dissolve in water, and dilute to 1 L.

**Potassium iodate**, 0.1*N* (5+ to 1–). Weigh out exactly 3.5667 g of  $\text{KIO}_3$  (free from iodide), dried at 120°C, and dissolve in water containing about 15 g of KI, and dilute to 1 L.

**Potassium permanganate**, 0.1*N* (7+ to 2+). Dissolve about 3.3 g in a liter of distilled water. Allow this to stand for 2 or 3 days, then siphon it carefully through clean glass tubes or filter it through a Gooch crucible into the glass container in which it is to be kept, discarding the first 25 mL and allowing the last inch of liquid to remain in the bottle. In this way any dust or reducing substance in the water is oxidized, and the  $\text{MnO}_2$  formed is removed. Permanganate solutions should never be allowed to come into contact with rubber, filter paper, or any other organic matter, and should be stored away from light. To standardize the  $\text{KMnO}_4$ , weigh accurately samples of about 0.3 g of primary standard grade  $\text{Na}_2\text{C}_2\text{O}_4$  into Erlenmeyer flasks, add 150 mL of distilled water and 4 mL of concentrated  $\text{H}_2\text{SO}_4$ , and heat to 70°C and maintain at this temperature throughout the titration with the permanganate solution. The end point is a faint, permanent pink color throughout the solution. Equivalent weight of  $\text{Na}_2\text{C}_2\text{O}_4/2$  is 67.000 g.

**Sodium thiosulfate**, 0.1*N*. Weigh 24.818 g of fresh crystals of  $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ , dissolve in distilled water. Add 0.5 g of  $\text{Na}_2\text{CO}_3$  and 0.5 mL of chloroform as preservative. Dilute to 1 L.

Equations for the principal methods for the redox determinations of the elements are given in Table 11.29. Volumetric factors in redox titrations for the common titrants are given in Table 11.28.

### 11.6.4 Indicators for Redox Titrations

A selected list of redox indicators will be found in Table 8.26. A redox indicator should be selected so that its  $E^0$  is approximately equal to the electrode potential at the equivalent point, or so that the color change will occur at an appropriate part of the titration curve. If  $n$  is the number of electrons involved in the transition from the reduced to the oxidized form of the indicator, the range in which the color change occurs is approximately given by  $E^0 \pm 0.06/n$  volt (V) for a two-color indicator whose forms are equally intensely colored. Since hydrogen ions are involved in the redox equilibria of many indicators, it must be recognized that the color change interval of such an indicator will vary with pH.

In Table 8.26,  $E^0$  represents the redox potential at which the color change of the indicator would normally be perceived in a solution containing approximately  $1\text{M H}^+$ . For a one-color indicator this is the potential at which the concentration of the colored form is just large enough to impart a visible color to the solution and depends on the total concentration of indicator added to the solution. If it is the reduced form of the indicator that is colorless, the potential at which the first visible color

appears becomes less positive as the total concentration of indicator increases. For a two-color indicator, the potential at which the middle tint appears is independent of the total indicator concentration, but may differ from the potentiometrically determined formal potential of the indicator in either direction, depending on which of the two forms is more intensely colored. If the reduced form is the more intense color, the middle tint will appear at a potential more positive than the potentiometrically measured formal potential, which is the potential at which the two forms are present at equal concentrations.

In addition to those indicators listed in Table 8.26, there are indicators for bromometric and iodometric titrations:

*Specific reagents for titrations with bromine or bromate*

|                             |                                                                                                   |
|-----------------------------|---------------------------------------------------------------------------------------------------|
| Methyl orange or methyl red | Use acid-base indicator solutions. Oxidation causes bleaching of indicator to colorless           |
| Bordeaux acid red 17        | Dissolve 2 g dye in 1 L water. The red solution is oxidized to pale yellowish green or colorless. |
| Naphthol blue black         | Dissolve 2 g dye in 1 L water. The blue solution is oxidized to pale red.                         |

*Specific reagents for iodometric titrations*

|                                                           |                                                                                                                                                                                                                                        |
|-----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Organic solvents such as $\text{CCl}_4$ , $\text{CHCl}_3$ | Up to 5 mL solvent is usually added per titration. Near the end point the mixture is shaken vigorously after each addition of titrant, and the appearance or disappearance of the $\text{I}_2$ color in the organic layer is observed. |
| Starch                                                    | Suspend 5 g of soluble starch in 50 mL of saturated NaCl solution, and stir slowly into 500 mL of boiling saturated NaCl solution. Cool and bottle. Free iodine produces a blue-black color.                                           |

### 11.6.5 Precipitation Titrations

Many precipitation reactions that are useful as separation techniques for gravimetric analysis fail to meet one or both of two requirements for titrimetry:

1. The reaction rate must be sufficiently rapid, particularly in the titration of dilute solutions and in the immediate vicinity of the end point. To increase the precipitation rate, it is sometimes beneficial to change solvents or to raise the temperature. By adding an excess of reagent and back-titrating, it may be possible to take advantage of a more rapid precipitation in the reverse direction. By choosing an end-point detection method that does not require equilibrium to be reached in the immediate vicinity of the end point, advantage may be taken of a faster reaction rate at points removed from the end point. Examples are: amperometric titrations, conductometric titrations, and photometric titrations.
2. The stoichiometry must be exact. Coprecipitation by solid-solution formation, foreign ion entrapment, and adsorption are possible sources of error.

Table 11.30 lists standard solutions for precipitation titrations and Table 11.31 lists specific reagents as indicators, adsorption indicators, and protective colloids for precipitation titrations.

### 11.6.6 Complexometric Titrations

A complexometric titration is based on the essentially stoichiometric reaction of a complexing agent (*chelon*) with another species to form a complex species (*chelonate*) that is only slightly dissociated and is soluble in the titration medium. In such a titration, either the chelon or the chelonate may serve as the limiting reagent (that is, as the titrant). The end point is detected by measuring or observing some property that reflects the change, in the vicinity of the equivalence point, in the concentration of the chelon or the chelonate. Examples of the application of metal-ion indicators are listed in Table 11.32. For a metal indicator to be useful, a proper sequence of effective stabilities must be met. On the one hand, the metal-indicator complex must be sufficiently stable to maintain itself in extremely dilute solution; otherwise the end-point color change will be spread over a broad interval of the titration, owing to the extended dissociation. On the other hand, the metal-indicator complex must be less stable than the metal chelonate; otherwise a sluggish end point, a late end point, or no end point at all will be obtained. Furthermore, the metal-indicator complex must react rapidly with the chelon. Only a limited number of the numerous chromogenic agents for metals allow this sequence and have useful indicator properties in chelometric titrations.

Among the complexing agents that find use as titrating agents, ethylenediamine-*N,N,N',N'*-tetraacetic acid (acronym EDTA, and equation abbreviation,  $H_4Y$ ) is by far the more important, and it is used in the vast majority of complexometric titrations. The successive acid  $pK_a$  values of  $H_4Y$  are  $pK_1 = 2.0$ ,  $pK_2 = 2.67$ ,  $pK_3 = 6.16$ ,  $pK_4 = 10.26$  at 20°C and an ionic strength of 0.1. The fraction  $\alpha_4$  present as the tetravalent anion is of particular importance in equilibrium calculations. Its magnitude at various pH values is given in Table 11.33.

The formation constants of EDTA complexes are gathered in Table 11.34. Based on their stability, the EDTA complexes of the most common metal ions may be roughly divided into three groups:

$\log K > 20$

Tri- and tetravalent cations including Bi, Fe(III), Ga, Hg(II), In, Sc, Th, U(IV), V(III), and Zr

$\log K = 15$  to 18

Divalent transition metals, rare earths, and Al

$\log K = 8$  to 11

Alkaline earths and Mg

The more stable the metal complex, the lower the pH at which it can be quantitatively formed. Elements in the first group may be titrated with EDTA at pH 1 to 3 without interference from cations of the last two groups, while cations of the second group may be titrated at pH 4 to 5 without interference from the alkaline earths.

In practice, an auxiliary complexing (masking) agent is usually added during EDTA titrations to prevent the precipitation of heavy metals as hydroxides or basic salts. The concentration of auxiliary complexing agents is generally high compared with the metal-ion concentration, and the solution is sufficiently well buffered so that the hydrogen ions produced during complexing of a metal ion by  $H_4Y$  do not cause an appreciable change in pH. Many EDTA titrations are carried out in ammonia–ammonium chloride buffers, which serve also to provide ammonia as an auxiliary complexing agent. The cumulative formation constants of ammine complexes are listed in Table 11.35.

**11.6.6.1 Types of Chelometric Titrations.** Chelometric titrations may be classified according to their manner of performance: direct titrations, back titrations, substitution titrations, redox titrations, or indirect methods.

**11.6.6.1.1 Direct Titrations.** The most convenient and simplest manner is the measured addition of a standard chelon solution to the sample solution (brought to the proper conditions of pH, buffer, etc.) until the metal ion is stoichiometrically chelated. Auxiliary complexing agents such as citrate, tartrate, or triethanolamine are added, if necessary, to prevent the precipitation of metal hydroxides or basic salts at the optimum pH for titration. For example, tartrate is added in the direct titration of lead. If a pH range of 9 to 10 is suitable, a buffer of ammonia and ammonium chloride is often added in relatively concentrated form, both to adjust the pH and to supply ammonia as an auxiliary complexing agent for those metal ions which form ammine complexes. A few metals, notably iron(III), bismuth, and thorium, are titrated in acid solution.

Direct titrations are commonly carried out using disodium dihydrogen ethylenediaminetetraacetate,  $Na_2H_2Y$ , which is available in pure form. The reaction of the chelon with the indicator must be rapid for a practical, direct titration. Where it is slow, heating of the titration medium is often expedient, or another indicator is employed.

**11.6.6.1.2 Back Titrations.** In the performance of a back titration, a known, but excess quantity of EDTA or other chelon is added, the pH is now properly adjusted, and the excess of the chelon is titrated with a suitable standard metal salt solution. Back titration procedures are especially useful when the metal ion to be determined cannot be kept in solution under the titration conditions or where the reaction of the metal ion with the chelon occurs too slowly to permit a direct titration, as in the titration of chromium(III) with EDTA. Back titration procedures sometimes permit a metal ion to be determined by the use of a metal indicator that is blocked by that ion in a direct titration. For example, nickel, cobalt, or aluminum form such stable complexes with Eriochrome Black T that the direct titration would fail. However, if an excess of EDTA is added before the indicator, no blocking occurs in the back titration with a magnesium or zinc salt solution. These metal ion titrants are chosen because they form EDTA complexes of relatively low stability, thereby avoiding the possible titration of EDTA bound by the sample metal ion.

In a back titration, a slight excess of the metal salt solution must sometimes be added to yield the color of the metal-indicator complex. Where metal ions are easily hydrolyzed, the complexing agent is best added at a suitable, low pH and only when the metal is fully complexed is the pH adjusted upward to the value required for the back titration. In back titrations, solutions of the following metal ions are commonly employed: Cu(II), Mg, Mn(II), Pb(II), Th(IV), and Zn. These solutions are usually prepared in the approximate strength desired from their nitrate salts (or the solution of the metal or its oxide or carbonate in nitric acid), and a minimum amount of acid is added to repress hydrolysis of the metal ion. The solutions are then standardized against an EDTA solution (or other chelon solution) of known strength.

**11.6.6.1.3 Substitution Titrations.** Upon the introduction of a substantial or equivalent amount of the chelonate of a metal that is less stable than that of the metal being determined, a substitution occurs, and the metal ion displaced can be titrated by the chelon in the same solution. This is a direct titration with regard to its performance, but in terms of the mechanism it can be considered as a substitution titration (or replacement titration).

In principle any ion can be used if it forms a weaker EDTA complex than the metal ion being determined. Still weaker metal-EDTA complexes would not interfere. Exchange reactions are also possible with other metal complexes to permit application of the chelometric titration to non-titrable cations and anions. The exchange reagent can be added and the titration performed in the sample solution without prior removal of the excess reagent. A most important example is the exchange of silver ion with an excess of the tetracyanonickelate ion according to the equation:

The nickel ion freed may then be determined by an EDTA titration. Note that two moles of silver are equivalent to one mole of nickel and thus to one mole of EDTA.

**11.6.6.1.4 Redox Titrations.** Redox titrations can be carried out in the presence of excess EDTA. Here EDTA acts to change the oxidation potential by forming a more stable complex with one oxidation state than with the other. Generally the oxidized form of the metal forms a more stable complex than the reduced form, and the couple becomes a stronger reducing agent in the presence of excess EDTA. For example, the Co(III)–Co(II) couple is shifted about 1.2 volts, so that Co(II) can be titrated with Ce(IV). Alternatively, Co(III) can be titrated to Co(II), with Cr(II) as a reducing agent.

Manganese(II) can be titrated directly to Mn(III) using hexacyanoferrate(III) as the oxidant. Alternatively, Mn(III), prepared by oxidation of the Mn(II)–EDTA complex with lead dioxide, can be determined by titration with standard iron(II) sulfate.

**11.6.6.1.5 Indirect Procedures.** Numerous inorganic anions that do not form complexes with a complexing agent are accessible to a chelometric titration by indirect procedures. Frequently the anion can be precipitated as a compound containing a stoichiometric amount of a titrable cation. Another indirect approach employing replacement mechanism is the reduction of a species with the liquid amalgam of a metal that can be determined by a chelometric titration after removal of excess amalgam. For example:

The equivalent amount of cadmium ion exchanged for the silver ion can readily be determined by EDTA titration procedures.

## 11.6.6.2 Preparation of Standard Solutions

**11.6.6.2.1 Standard EDTA Solutions.** Disodium dihydrogen ethylenediaminetetraacetate dihydrate is available commercially of analytical reagent purity. After drying at 80°C for at least 24 hr, its composition agrees exactly with the dihydrate formula (molecular weight 372.25). It may be weighed directly. If an additional check on the concentration is required, it may be standardized by titration with nearly neutralized zinc chloride or zinc sulfate solution.

**11.6.6.2.2 Standard Magnesium Solution.** Dissolve 24.647 g of magnesium sulfate heptahydrate in water and dilute to 1 L for 0.1M solution.

**11.6.6.2.3 Standard Manganese(II) Solution.** Dissolve exactly 16.901 g ACS reagent grade manganese(II) sulfate hydrate in water and dilute to 1 L.

**11.6.6.2.4 Standard Zinc Solution.** Dissolve exactly 13.629 g of zinc chloride, ACS reagent grade, or 28.754 g of zinc sulfate heptahydrate, and dilute to 1 L for 0.1000M solution.

**11.6.6.2.5 Buffer Solution, pH 10.** Add 142 mL of concentrated ammonia solution (sp. grav. 0.88–0.90) to 17.5 g of analytical reagent ammonium chloride, and dilute to 250 mL.

**11.6.6.2.6 Water.** Distilled water must be (a) redistilled in an all-Pyrex glass apparatus or (b) purified by passage through a column of cation exchange resin in the sodium form. For storage, polyethylene bottles are most satisfactory, particularly for very dilute (0.001M) EDTA solutions.

**11.6.6.2.7 Murexide Indicator.** Suspend 0.5 g of powdered murexide in water, shake thoroughly, and allow the undissolved solid to settle. Use 5–6 drops of the supernatant liquid for each titration. Decant the old supernatant liquid daily and treat the residue with water to provide a fresh solution of the indicator.

Alternatively, grind 0.1 g of murexide with 10 g of ACS reagent grade sodium chloride; use about 50 mg of the mixture for each titration.

**11.6.6.2.8 Pyrocatechol Violet Indicator Solution.** Dissolve 0.1 g of the solid dyestuff in 100 mL of water.

## 11.6.7 Masking Agents

Masking (and demasking) techniques are widely used in analytical chemistry because they frequently provide convenient and elegant methods by which to avoid the effects of unwanted components of a system without having to resort to physical separation. The best molecules or ligands to use as masking agents are those that are chemically stable and nontoxic and react rapidly to form strong, colorless complexes with the ions to be masked, but form only relatively weak complexes with other ions that are present. Tables 11.36 and 11.37 are intended as qualitative guides to the types of masking agents likely to be suitable for particular analytical problems.

Masking must not be identified solely with complex formation. There are numerous complex compounds in which solutions show no masking effects. On the other hand, examples can be cited in which the product of soluble principal valence compounds may lead to masking. This latter category includes the annulment of the base action of  $\text{NH}_2$ — groups in carboxylic acids by the addition of formaldehyde, the masking of the iodometric oxidation of sulfites by formaldehyde, as well as the masking of almost all reactions of molybdenum(VI), tungsten(VI), and vanadium(V) by hydrogen peroxide or fluoride ion. Sometimes the masking agent changes the valence state of the metal ion. Examples include the reduction of Fe(III) to Fe(II) with hydrazine, hydroxylamine hydrochloride, or tin(II) chloride. Hydroxylamine also reduces Ce(IV) to Ce(III), Cu(II) to Cu(I), and Hg(II) to free Hg. Ascorbic acid reduces Cu(II) to Cu(I) in the presence of the chloride ion.

The reaction of the hydrogen sulfite ion in an alkaline solution with ketones and aldehydes is:

The carbon-oxygen double bond of the carbonyl group is opened, and the hydrogen sulfite radical is added. An increase in temperature reverses the reaction more easily for ketones than for aldehydes.

Certain organic substances have no charge at any pH but form complexes with substances that do have a charge. The sugars and polyalcohols form such complexes in the pH range between 9 and 10 with a number of anions; including borate, molybdate, and arsenite. Elegant ion exchange methods have been devised for the sugars.

Probably the most extensively applied masking agent is cyanide ion. In alkaline solution, cyanide forms strong cyano complexes with the following ions and masks their action toward EDTA: Ag, Cd, Co(II), Cu(II), Fe(II), Hg(II), Ni, Pd(II), Pt(II), Tl(III), and Zn. The alkaline earths, Mn(II), Pb, and the rare earths are virtually unaffected; hence, these latter ions may be titrated with EDTA with the former ions masked by cyanide. Iron(III) is also masked by cyanide. However, as the hexacyanoferrate(III) ion oxidizes many indicators, ascorbic acid is added to form hexacyanoferrate(II) ion. Moreover, since the addition of cyanide to an acidic solution results in the formation of deadly

hydrogen cyanide, the solution must first be made alkaline, with hydrous oxide formation prevented by the addition of tartrate. Zinc and cadmium may be demasked from their cyanide complexes by the action of formaldehyde.

Masking by oxidation or reduction of a metal ion to a state which does not react with EDTA is occasionally of value. For example, Fe(III) ( $\log K_{MY} = 24.23$ ) in acidic media may be reduced to Fe(II) ( $\log K_{MY} = 14.33$ ) by ascorbic acid; in this state iron does not interfere in the titration of some trivalent and tetravalent ions in strong acidic medium (pH 0 to 2). Similarly, Hg(II) can be reduced to the metal. In favorable conditions, Cr(III) may be oxidized by alkaline peroxide to chromate which does not complex with EDTA.

In resolving complex metal-ion mixtures, more than one masking or demasking process may be utilized with various aliquots of the sample solution, or applied simultaneously or stepwise with a single aliquot. In favorable cases, even four or five metals can be determined in a mixture by the application of direct and indirect masking processes. Of course, not all components of the mixture need be determined by chelometric titrations. For example, redox titrimetry may be applied to the determination of one or more of the metals present.

### 11.6.8 Demasking

For the major part, masking reactions that occur in solutions and lead to soluble compounds are equilibrium reactions. They usually require the use of an excess of the masking agent and can be reversed again by removal of the masking agent. The freeing of previously masked ionic or molecular species has been called *demasking*. This merits consideration in regard to its use in analysis. Masking never completely removes certain ionic or molecular species, but only reduces their concentrations. The extent of this lowering determines which color or precipitation reactions can be prevented. A system masked against a certain reagent is not necessarily masked against another but more aggressive reagent. It is therefore easy to see that masked reaction systems can also function as reagents at times (e.g., Fehling's solution, Nessler's reagent).

The methods used in demasking are varied. One approach is to change drastically the hydrogen ion concentration of the solution. The conditional stability constants of most metal complexes depend greatly on pH, so that simply raising or lowering the pH is frequently sufficient for selective demasking. In most cases a strong mineral acid is added, and the ligand is removed from the coordination sphere of the complex through the formation of a slightly ionized acid, as with the polyprotic (citric, tartaric, EDTA, and nitriloacetic) acids.

Another type of demasking involves formation of new complexes or other compounds that are more stable than the masked species. For example, boric acid is used to demask fluoride complexes of tin(IV) and molybdenum(VI). Formaldehyde is often used to remove the masking action of cyanide ions by converting the masking agent to a nonreacting species through the reaction:

which forms glycolic nitrile. Pertinent instances are the demasking of  $\text{Ni}(\text{CN})_4^{2-}$  ions to  $\text{Ni}^{2+}$  ions by formaldehyde and the demasking of dimethylglyoxime (dmg) from  $\text{Pd}(\text{dmg})_2^{2-}$  ions by cyanide. Selectivity is evident in that  $\text{Zn}(\text{CN})_4^{2-}$  is demasked whereas  $\text{Cu}(\text{CN})_3^-$  is not.

Destruction of the masking ligand by chemical reaction may be possible, as in the oxidation of EDTA in acid solutions by permanganate or another strong oxidizing agent. Hydrogen peroxide and Cu(II) ion destroy the tartrate complex of aluminum.

Demasking methods for a number of masking agents are enumerated in Table 11.38.

**TABLE 11.30** Standard Solutions for Precipitation Titrations

The list given below includes the substances that are most used and most useful for the standardization of solutions for precipitation titrations. Primary standard solutions are denoted by the letter (P) in Column 1.

| Standard                                                 | Formula weight | Preparation                                                                                                                                                                                                                                             |
|----------------------------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AgNO <sub>3</sub> (P)                                    | 169.89         | Weigh the desired amount of ACS reagent grade* AgNO <sub>3</sub> , dried at 105°C for 2 hr, and dissolve in double distilled water. Store in amber container and away from light. Check against NaCl.                                                   |
| BaCl <sub>2</sub> · 2H <sub>2</sub> O                    | 244.28         | Dissolve clear crystals of the salt in distilled water. Standardize against K <sub>2</sub> SO <sub>4</sub> or Na <sub>2</sub> SO <sub>4</sub> .                                                                                                         |
| Hg(NO <sub>3</sub> ) <sub>2</sub> · H <sub>2</sub> O     | 342.62         | Dissolve the reagent grade salt in distilled water and dilute to desired volume. Standardize against NaCl.                                                                                                                                              |
| KBr                                                      | 119.01         | The commercial reagent (ACS) may contain 0.2% chloride. Prepare an aqueous solution of approximately the desired concentration and standardize it against AgNO <sub>3</sub> .                                                                           |
| K <sub>4</sub> [Fe(CN)] <sub>6</sub> · 3H <sub>2</sub> O | 422.41         | Dissolve the high-purity commercial salt in distilled water containing 0.2 g/L of Na <sub>2</sub> CO <sub>3</sub> . Kept in an amber container and away from direct sunlight, solutions are stable for a month or more. Standardize against zinc metal. |
| KSCN                                                     | 97.18          | Prepare aqueous solutions having the concentration desired. Standardize against AgNO <sub>3</sub> solution. Protect from direct sunlight.                                                                                                               |
| K <sub>2</sub> SO <sub>4</sub> (P)                       | 174.26         | Dissolve about 17.43 g, previously dried at 150°C and accurately weighed, in distilled water and dilute exactly to 1 L.                                                                                                                                 |
| NaCl (P)                                                 | 58.44          | Dry at 130–150°C and weigh accurately, from a closed container, 5.844 g, dissolve in water, and dilute exactly to 1 L.                                                                                                                                  |
| NaF (P)                                                  | 41.99          | Dry at 110°C and weigh the appropriate amount of ACS reagent. Dissolve in water and dilute exactly to 1 L.                                                                                                                                              |
| Na <sub>2</sub> SO <sub>4</sub> (P)                      | 142.04         | Weigh accurately 14.204 g, dried at 150°C, and dissolve in distilled water. Dilute to exactly 1 L.                                                                                                                                                      |
| Th(NO <sub>3</sub> ) <sub>4</sub> · 4H <sub>2</sub> O    | 552.12         | Weigh the appropriate amount of crystals and dissolve in water. Standardize against NaF.                                                                                                                                                                |

\* Meets standards of purity (and impurity) set by the American Chemical Society.

**TABLE 11.31** Indicators for Precipitation Titrations

| Indicator                                                        | Preparation and use                                                                                                                                                                                                              |
|------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specific reagents                                                |                                                                                                                                                                                                                                  |
| $\text{NH}_4\text{Fe}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ | Use reagent (ACS)* grade salt, low in chloride. Dissolve 175 g in 100 mL 6 M $\text{HNO}_3$ which has been gently boiled for 10 min to expel nitrogen oxides. Dilute with 500 mL water. Use 2 mL per 100 mL of end-point volume. |
| $\text{K}_2\text{CrO}_4$                                         | Use reagent (ACS)* grade salt, low in chloride. Prepare 0.1M aqueous solution (19.421 g/L). Use 2.5 mL per 100 mL of end-point volume.                                                                                           |
| Tetrahydroxy-1,4-benzoquinone (THQ)                              | Prepare fresh as required by dissolving 15 mg in 5 mL of water. Use 10 drops for each titration.                                                                                                                                 |
| Adsorption indicators                                            |                                                                                                                                                                                                                                  |
| Bromophenol blue                                                 | Dissolve 0.1 g of the acid in 200 mL 95% ethanol.                                                                                                                                                                                |
| 2',7'-Dichlorofluorescein                                        | Dissolve 0.1 g of the acid in 100 mL 70% ethanol. Use 1 mL for 100 mL of initial solution.                                                                                                                                       |
| Eosin, tetrabromofluorescein                                     | See Dichlorofluorescein.                                                                                                                                                                                                         |
| Fluorescein                                                      | Dissolve 0.4 g of the acid in 200 mL 70% ethanol. Use 10 drops.                                                                                                                                                                  |
| Potassium rhodizonate, $\text{C}_4\text{O}_4(\text{OK})_2$       | Prepare fresh as required by dissolving 15 mg in 5 mL of water. Use 10 drops for each titration.                                                                                                                                 |
| Rhodamine 6G                                                     | Dissolve 0.1 g in 200 mL 70% ethanol.                                                                                                                                                                                            |
| Sodium 3-alizarinsulfonate                                       | Prepare a 0.2% aqueous solution. Use 5 drops per 120 mL end-point volume.                                                                                                                                                        |
| Thorin                                                           | Prepare a 0.025% aqueous solution. Use 5 drops.                                                                                                                                                                                  |
| Protective colloids                                              |                                                                                                                                                                                                                                  |
| Dextrin                                                          | Use 5 mL of 2% aqueous solution of chloride-free dextrin per 25 mL of 0.1M halide solution.                                                                                                                                      |
| Polyethylene glycol 400                                          | Prepare a 50% (v/v) aqueous solution of the surfactant. Use 5 drops per 100 mL end-point volume.                                                                                                                                 |

TABLE 11.38 Common Demasking Agents

Abbreviations: DPC, diphenylcarbazide; HDMG, dimethylglyoxime; PAN, 1-(2-pyridylazo)-2-naphthol.

| Complexing agent | Ion demasked     | Demasking agent        | Application                                  |
|------------------|------------------|------------------------|----------------------------------------------|
| CN <sup>-</sup>  | Ag <sup>+</sup>  | H <sup>+</sup>         | Precipitation of Ag                          |
|                  | Cd <sup>2+</sup> | H <sup>+</sup>         | Free Cd <sup>2+</sup>                        |
|                  |                  | HCHO + OH <sup>-</sup> | Detection of Cd (with DPC) in presence of Cu |
|                  |                  | H <sup>+</sup>         | Precipitation of Cu                          |
|                  | Cu <sup>2+</sup> | HgO                    | Determination of Cu                          |
|                  | Fe <sup>2+</sup> | Hg <sup>2+</sup>       | Free Fe <sup>2+</sup>                        |
|                  | Fe <sup>3+</sup> | HgO                    | Determination of Fe                          |
|                  |                  |                        |                                              |

**TABLE 11.38** Common Demasking Agents (*Continued*)

| Complexing agent                                                                                     | Ion demasked          | Demasking agent                                     | Application                                                                             |
|------------------------------------------------------------------------------------------------------|-----------------------|-----------------------------------------------------|-----------------------------------------------------------------------------------------|

**TABLE 11.39** Amino Acids pI and pK<sub>a</sub> Values

This table lists the pK<sub>a</sub> and pI (pH at the isoelectric point) values of α-amino acids commonly found in proteins along with their abbreviations. The dissociation constants refer to aqueous solutions at 25°C.

| Name          | Abbreviations |          | pK <sub>a</sub> values |                               |              | pI values |
|---------------|---------------|----------|------------------------|-------------------------------|--------------|-----------|

**TABLE 11.43** Buret Accuracy Tolerances

| Capacity, mL | Subdivision, mL | Accuracy, $\pm$ mL           |                            |
|--------------|-----------------|------------------------------|----------------------------|
|              |                 | Class A* and precision grade | Class B and standard grade |
| 10           | 0.05            | 0.02                         | 0.04                       |
| 25           | 0.10            | 0.03                         | 0.06                       |
| 50           | 0.10            | 0.05                         | 0.10                       |
| 100          | 0.20            | 0.10                         | 0.20                       |

\* Class A conforms to specifications in ASTM E694 for standard taper stopcocks and to ASTM E287 for Teflon or polytetrafluoroethylene stopcock plugs. The 10-mL size meets the requirements for ASTM D664.

**TABLE 11.44** Factors for Simplified Computation of Volume

The volume is determined by weighing the water, having a temperature of  $t^{\circ}\text{C}$ , contained or delivered by the apparatus at the same temperature. The weight of water,  $w$  grams, is obtained with brass weights in air having a density of 1.20 mg/mL.

For apparatus made of soft glass, the volume contained or delivered at  $20^{\circ}\text{C}$  is given by

$$\nu_{20} = wf_{20} \text{ mL}$$

where  $\nu_{20}$  is the volume at  $20^{\circ}$  and  $f_{20}$  is the factor (apparent specific volume) obtained from the table below for the temperature  $t$  at which the calibration is performed. The volume at any other temperature  $t'$  may then be obtained from

$$\nu' = \nu_{20}[1 + 0.00002(t' - 20)] \text{ mL}$$

For apparatus made of any other material, the volume contained or delivered at the temperature  $t$  is

$$\nu_t = wf_t \text{ mL}$$

where  $w$  is again the weight in air obtained with brass weights (in grams), and  $f_t$  is the factor given in the third column of the table for the temperature  $t$ . The volume at any temperature  $t'$  may then be obtained from

$$\nu'_t = \nu_t[1 + \beta(t' - t)] \text{ mL}$$

where  $\beta$  is the cubical coefficient of thermal expansion of the material from which the apparatus is made. Approximate values of  $\beta$  for some frequently encountered materials are given in Table 11.45.

| $t, ^{\circ}\text{C}$ | $f_{20}$ | $f_t$    | $t, ^{\circ}\text{C}$ | $f_{20}$ | $f_t$    |
|-----------------------|----------|----------|-----------------------|----------|----------|

**TABLE 11.45** Cubical Coefficients of Thermal Expansion

This table lists values of  $\beta$ , the cubical coefficient of thermal expansion, taken from “Essentials of Quantitative Analysis,” by Benedetti-Pichler, and from various other sources. The value of  $\beta$  represents the relative increases in volume for a change in temperature of 1°C at temperatures in the vicinity of 25°C, and is equal to  $3\alpha$ , where  $\alpha$  is the linear coefficient of thermal expansion. Data are given for the types of glass from which volumetric apparatus is most commonly made, and also for some other materials which have been or may be used in the fabrication of apparatus employed in analytical work.

| Material                            | $\beta$               |
|-------------------------------------|-----------------------|
| <b>Glasses</b>                      |                       |
| Alkali-resistant, Corning 728       | $1.90 \times 10^{-5}$ |
| Gerateglas, Schott G20              | 1.47                  |
| Kimble KG-33 (borosilicate)         | 0.96                  |
| N-51A (“Resistant”)                 | 1.47                  |
| R-6 (soft)                          | 2.79                  |
| Pyrex, Corning 744                  | 0.96                  |
| Vitreous silica                     | 0.15                  |
| Vycor, Corning 790                  | 0.24                  |
| <b>Metals</b>                       |                       |
| Brass                               | ca. 5.5               |
| Copper                              | 5.0                   |
| Gold                                | 4.3                   |
| Monel metal                         | 4.0                   |
| Platinum                            | 2.7                   |
| Silver                              | 5.7                   |

| Tantalum                            | ca. 2.0               |
| Tungsten                            | 1.3                   |
| <b>Plastics and other materials</b> |                       |
| Hard rubber                         | $24 \times 10^{-5}$   |
| Polyethylene                        | 45–90                 |
| Polystyrene                         | 18–24                 |
| Porcelain                           | ca. 1.2               |
| Teflon (polytetrafluoroethylene)    | 16.5                  |

**TABLE 11.46** General Solubility Rules for Inorganic Compounds

|                                              |                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Nitrates                                     | All nitrates are soluble.                                                                                                                                                                                                                                                                                                                 |
| Acetates                                     | All acetates are soluble; silver acetate is moderately soluble.                                                                                                                                                                                                                                                                           |
| Chlorides                                    | All chlorides are soluble except AgCl, PbCl <sub>2</sub> , and Hg <sub>2</sub> Cl <sub>2</sub> . PbCl <sub>2</sub> is soluble in hot water, slightly soluble in cold water.                                                                                                                                                               |
| Sulfates                                     | All sulfates are soluble except barium and lead. Silver, mercury(I), and calcium are only slightly soluble.                                                                                                                                                                                                                               |
| Hydrogen sulfates                            | The hydrogen sulfates are more soluble than the sulfates.                                                                                                                                                                                                                                                                                 |
| Carbonates, phosphates, chromates, silicates | All carbonates, phosphates, chromates, and silicates are insoluble, except those of sodium, potassium, and ammonium. An exception is MgCrO <sub>4</sub> which is soluble.                                                                                                                                                                 |
| Hydroxides                                   | All hydroxides (except lithium, sodium, potassium, cesium, rubidium, and ammonia) are insoluble; Ba(OH) <sub>2</sub> is moderately soluble; Ca(OH) <sub>2</sub> and Sr(OH) <sub>2</sub> are slightly soluble.                                                                                                                             |
| Sulfides                                     | All sulfides (except alkali metals, ammonium, magnesium, calcium, and barium) are insoluble. Aluminum and chromium sulfides are hydrolyzed and precipitate as hydroxides.                                                                                                                                                                 |
| Sodium, potassium, ammonium                  | All sodium, potassium, and ammonium salts are soluble. Exceptions: Na <sub>4</sub> Sb <sub>2</sub> O <sub>7</sub> , K <sub>2</sub> NaCo(NO <sub>2</sub> ) <sub>6</sub> , K <sub>2</sub> PtCl <sub>6</sub> , (NH <sub>4</sub> ) <sub>2</sub> PtCl <sub>6</sub> , and (NH <sub>4</sub> ) <sub>2</sub> NaCo(NO <sub>2</sub> ) <sub>6</sub> . |
| Silver                                       | All silver salts are insoluble. Exceptions: AgNO <sub>3</sub> and AgClO <sub>4</sub> ; AgC <sub>2</sub> H <sub>3</sub> O <sub>2</sub> and Ag <sub>2</sub> SO <sub>4</sub> are moderately soluble.                                                                                                                                         |

11.7 LABORATORY SOLUTIONS

TABLE 11.47 Concentrations of Commonly Used Acids and Bases

Freshly opened bottles of these reagents are generally of the concentrations indicated in the table. This may not be true of bottles long opened and this is especially true of ammonium hydroxide, which rapidly loses its strength. In preparing volumetric solutions, it is well to be on the safe side and take a little more than the calculated volume of the concentrated reagent, since it is much easier to dilute a concentrated solution than to strengthen one that is too weak.

A concentrated C.P. reagent usually comes to the laboratory in a bottle having a label which states its molecular weight  $w$ , its density (or its specific gravity)  $d$ , and its percentage assay  $p$ . When such a reagent is used to prepare an aqueous solution of desired molarity  $M$ , a convenient formula to employ is

$$V = \frac{100 \text{ } wM}{pd}$$

where  $V$  is the number of milliliters of concentrated reagent required for 1 liter of the dilute solution.

*Example:* Sulfuric acid has the molecular weight 98.08. If the concentrated acid assays 95.5% and has the specific gravity 1.84, the volume required for 1 liter of a 0.1 molar solution is

$$V = \frac{100 \times 98.08 \times 0.1}{95.5 \times 1.84} = 5.58 \text{ mL}$$

| Reagent                                  | Formula Weight | Density, g · mL <sup>-1</sup> (20°C) | Weight % (approx) | Molarity | V, mL* |
|------------------------------------------|----------------|--------------------------------------|-------------------|----------|--------|
| Acetic acid                              | 60.05          | 1.05                                 | 99.8              | 17.45    | 57.3   |
| Ammonium hydroxide (as NH <sub>3</sub> ) | 35.05<br>17.03 | 0.90                                 | 56.6<br>28.0      | 14.53    | 60.0   |
| Ethylenediamine                          | 60.10          | 0.899                                | 100               | 15.0     | 66.7   |
| Formic acid                              | 46.03          | 1.20                                 | 90.5              | 23.6     | 42.5   |
| Hydrazine                                | 32.05          | 1.011                                | 95                | 30.0     | 33.3   |
| Hydriodic acid                           | 127.91         | 1.70                                 | 57                | 7.6      | 132    |

| Hydrofluoric acid                        | 20.0           | 1.18                                 | 49.0              | 28.9     | 34.5   |
| Nitric acid                              | 63.01          | 1.42                                 | 70.4              | 15.9     | 63.0   |
| Perchloric acid                          | 100.47         | 1.67                                 | 70.5              | 11.7     | 85.5   |
| Phosphoric acid                          | 97.10          | 1.70                                 | 85.5              | 14.8     | 67.5   |
| Pyridine                                 | 79.10          | 0.982                                | 100               | 12.4     | 80.6   |
| Potassium hydroxide (soln)               | 56.11          | 1.46                                 | 45                | 11.7     | 85.5   |
| Sodium hydroxide (soln)                  | 40.00          | 1.54                                 | 50.5              | 19.4     | 51.5   |
| Sulfuric acid                            | 98.08          | 1.84                                 | 96.0              | 18.0     | 55.8   |
| Triethanolamine                          | 149.19         | 1.124                                | 100               | 7.53     | 132.7  |

\* V, mL = volume in milliliters needed to prepare 1 liter of 1 molar solution.

**TABLE 11.48** Standard Stock Solutions\*

| Element    | Procedure                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Aluminum   | Dissolve 1.000 g Al wire in minimum amount of 2 M HCl; dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Antimony   | Dissolve 1.000 g Sb in (1) 10 ml HNO <sub>3</sub> plus 5 ml HCl, and dilute to volume when dissolution is complete; or (2) 18 ml HBr plus 2 ml liquid Br <sub>2</sub> ; when dissolution is complete add 10 ml HClO <sub>4</sub> , heat in a well-ventilated hood while swirling until white fumes appear and continue for several minutes to expel all HBr, then cool and dilute to volume.                                                                                                                                                                                              |
| Arsenic    | Dissolve 1.3203 g of As <sub>2</sub> O <sub>3</sub> in 3 ml 8 M HCl and dilute to volume; or treat the oxide with 2 g NaOH and 20 ml water; after dissolution dilute to 200 ml, neutralize with HCl (pH meter), and dilute to volume.                                                                                                                                                                                                                                                                                                                                                     |
| Barium     | (1) Dissolve 1.7787 g BaCl <sub>2</sub> · 2H <sub>2</sub> O (fresh crystals) in water and dilute to volume. (2) Dissolve 1.516 g BaCl <sub>2</sub> (dried at 250°C for 2 hr) in water and dilute to volume. (3) Treat 1.4367 g BaCO <sub>3</sub> with 300 ml water, slowly add 10 ml of HCl and, after the CO <sub>2</sub> is released by swirling, dilute to volume.                                                                                                                                                                                                                     |
| Beryllium  | (1) Dissolve 19.655 g BeSO <sub>4</sub> · 4H <sub>2</sub> O in water, add 5 ml HCl (or HNO <sub>3</sub> ), and dilute to volume. (2) Dissolve 1.000 g Be in 25 ml 2 M HCl, then dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                         |
| Bismuth    | Dissolve 1.000 g Bi in 8 ml of 10 M HNO <sub>3</sub> , boil gently to expel brown fumes, and dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Boron      | Dissolve 5.720 g fresh crystals of H <sub>3</sub> BO <sub>3</sub> and dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Bromine    | Dissolve 1.489 g KBr (or 1.288 g NaBr) in water and dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Cadmium    | (1) Dissolve 1.000 g Cd in 10 ml of 2 M HCl; dilute to volume. (2) Dissolve 2.282 g 3CdSO <sub>4</sub> · 8H <sub>2</sub> O in water; dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Calcium    | Place 2.4973 g CaCO <sub>3</sub> in volumetric flask with 300 ml water, carefully add 10 ml HCl; after CO <sub>2</sub> is released by swirling, dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Cerium     | (1) Dissolve 4.515 g (NH <sub>4</sub> ) <sub>4</sub> Ce(SO <sub>4</sub> ) <sub>4</sub> · 2H <sub>2</sub> O in 500 ml water to which 30 ml H <sub>2</sub> SO <sub>4</sub> had been added, cool, and dilute to volume. Advisable to standardize against As <sub>2</sub> O <sub>3</sub> . (2) Dissolve 3.913 g (NH <sub>4</sub> ) <sub>2</sub> Ce(NO <sub>3</sub> ) <sub>6</sub> in 10 ml H <sub>2</sub> SO <sub>4</sub> , stir 2 min, cautiously introduce 15 ml water and again stir 2 min. Repeat addition of water and stirring until all the salt has dissolved, then dilute to volume. |
| Cesium     | Dissolve 1.267 g CsCl and dilute to volume. Standardize: Pipette 25 ml of final solution to Pt dish, add 1 drop H <sub>2</sub> SO <sub>4</sub> , evaporate to dryness, and heat to constant weight at > 800°C. Cs (in µg/ml) = (40)(0.734)(wt of residue)                                                                                                                                                                                                                                                                                                                                 |
| Chlorine   | Dissolve 1.648 g NaCl and dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Chromium   | (1) Dissolve 2.829 g K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> in water and dilute to volume. (2) Dissolve 1.000 g Cr in 10 ml HCl, and dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Cobalt     | Dissolve 1.000 g Co in 10 ml of 2 M HCl, and dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Copper     | (1) Dissolve 3.929 g fresh crystals of CuSO <sub>4</sub> · 5H <sub>2</sub> O, and dilute to volume. (2) Dissolve 1.000 g Cu in 10 ml HCl plus 5 ml water to which HNO <sub>3</sub> (or 30%H <sub>2</sub> O <sub>2</sub> ) is added dropwise until dissolution is complete. Boil to expel oxides of nitrogen and chlorine, then dilute to volume.                                                                                                                                                                                                                                          |
| Dysprosium | Dissolve 1.1477 g Dy <sub>2</sub> O <sub>3</sub> in 50 ml of 2 M HCl; dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Erbium     | Dissolve 1.1436 g Er <sub>2</sub> O <sub>3</sub> in 50 ml of 2 M HCl; dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Europium   | Dissolve 1.1579 g Eu <sub>2</sub> O <sub>3</sub> in 50 ml of 2 M HCl; dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Fluorine   | Dissolve 2.210 g NaF in water and dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Gadolinium | Dissolve 1.152 g Gd <sub>2</sub> O <sub>3</sub> in 50 ml of 2 M HCl; dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Gallium    | Dissolve 1.000 g Ga in 50 ml of 2 M HCl; dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Germanium  | Dissolve 1.4408 g GeO <sub>2</sub> with 50 g oxalic acid in 100 ml of water; dilute to volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

\* 1000 µg/mL as the element in a final volume of 1 liter unless stated otherwise.

From J. A. Dean and T. C. Rains, "Standard Solutions for Flame Spectrometry," in *Flame Emission and Atomic Absorption Spectrometry*, J. A. Dean and T. C. Rains (Eds.), Vol. 2, Chap. 13, Marcel Dekker, New York, 1971.

**TABLE 11.48** Standard Stock Solutions (*Continued*)

| Element      | Procedure                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Gold         | Dissolve 1.000 g Au in 10 ml of hot $\text{HNO}_3$ by dropwise addition of $\text{HCl}$ , boil to expel oxides of nitrogen and chlorine, and dilute to volume. Store in amber container away from light.                                                                                                                                                                                                            |
| Hafnium      | Transfer 1.000 g Hf to Pt dish, add 10 ml of 9 M $\text{H}_2\text{SO}_4$ , and then slowly add $\text{HF}$ dropwise until dissolution is complete. Dilute to volume with 10% $\text{H}_2\text{SO}_4$ .                                                                                                                                                                                                              |
| Holmium      | Dissolve 1.1455 g $\text{Ho}_2\text{O}_3$ in 50 ml of 2 M $\text{HCl}$ ; dilute to volume.                                                                                                                                                                                                                                                                                                                          |
| Indium       | Dissolve 1.000 g In in 50 ml of 2 M $\text{HCl}$ ; dilute to volume.                                                                                                                                                                                                                                                                                                                                                |
| Iodine       | Dissolve 1.308 g $\text{KI}$ in water and dilute to volume.                                                                                                                                                                                                                                                                                                                                                         |
| Iridium      | (1) Dissolve 2.465 g $\text{Na}_3\text{IrCl}_6$ in water and dilute to volume. (2) Transfer 1.000 g Ir sponge to a glass tube, add 20 ml of $\text{HCl}$ and 1 ml of $\text{HClO}_4$ . Seal the tube and place in an oven at $300^\circ\text{C}$ for 24 hr. Cool, break open the tube, transfer the solution to a volumetric flask, and dilute to volume. Observe all safety precautions in opening the glass tube. |
| Iron         | Dissolve 1.000 g Fe wire in 20 ml of 5 M $\text{HCl}$ ; dilute to volume.                                                                                                                                                                                                                                                                                                                                           |
| Lanthanum    | Dissolve 1.1717 g $\text{La}_2\text{O}_3$ (dried at $110^\circ\text{C}$ ) in 50 ml of 5 M $\text{HCl}$ , and dilute to volume.                                                                                                                                                                                                                                                                                      |
| Lead         | (1) Dissolve 1.5985 g $\text{Pb}(\text{NO}_3)_2$ in water plus 10 ml $\text{HNO}_3$ , and dilute to volume. (2) Dissolve 1.000 g Pb in 10 ml $\text{HNO}_3$ , and dilute to volume.                                                                                                                                                                                                                                 |
| Lithium      | Dissolve a slurry of 5.3228 g $\text{Li}_2\text{CO}_3$ in 300 ml of water by addition of 15 ml $\text{HCl}$ ; after release of $\text{CO}_2$ by swirling, dilute to volume.                                                                                                                                                                                                                                         |
| Lutetium     | Dissolve 1.6079 g $\text{LuCl}_3$ in water and dilute to volume.                                                                                                                                                                                                                                                                                                                                                    |
| Magnesium    | Dissolve 1.000 g Mg in 50 ml of 1 M $\text{HCl}$ and dilute to volume.                                                                                                                                                                                                                                                                                                                                              |
| Manganese    | (1) Dissolve 1.000 g Mn in 10 ml $\text{HCl}$ plus 1 ml $\text{HNO}_3$ , and dilute to volume. (2) Dissolve 3.0764 g $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ (dried at $105^\circ\text{C}$ for 4 hr) in water and dilute to volume. (3) Dissolve 1.5824 g $\text{MnO}_2$ in 10 $\text{HCl}$ in a good hood, evaporate to gentle dryness, dissolve residue in water and dilute to volume.                           |
| Mercury      | Dissolve 1.000 g Hg in 10 ml of 5 M $\text{HNO}_3$ and dilute to volume.                                                                                                                                                                                                                                                                                                                                            |
| Molybdenum   | (1) Dissolve 2.0425 g $(\text{NH}_4)_2\text{MoO}_4$ in water and dilute to volume. (2) Dissolve 1.5003 g $\text{MoO}_3$ in 100 ml of 2 M ammonia, and dilute to volume.                                                                                                                                                                                                                                             |
| Neodymium    | Dissolve 1.7373 g $\text{NdCl}_3$ in 100 ml 1 M $\text{HCl}$ and dilute to volume.                                                                                                                                                                                                                                                                                                                                  |
| Nickel       | Dissolve 1.000 g Ni in 10 ml hot $\text{HNO}_3$ , cool, and dilute to volume.                                                                                                                                                                                                                                                                                                                                       |
| Niobium      | Transfer 1.000 g Nb (or 1.4305 g $\text{Nb}_2\text{O}_5$ ) to Pt dish, add 20 ml $\text{HF}$ , and heat gently to complete dissolution. Cool, add 40 ml $\text{H}_2\text{SO}_4$ , and evaporate to fumes of $\text{SO}_3$ . Cool and dilute to volume with 8 M $\text{H}_2\text{SO}_4$ .                                                                                                                            |
| Osmium       | Dissolve 1.3360 g $\text{OsO}_4$ in water and dilute to 100 ml. Prepare only as needed as solution loses strength on standing unless Os is reduced by $\text{SO}_2$ and water is replaced by 100 ml 0.1 M $\text{HCl}$ .                                                                                                                                                                                            |
| Palladium    | Dissolve 1.000 g Pd in 10 ml of $\text{HNO}_3$ by dropwise addition of $\text{HCl}$ to hot solution; dilute to volume.                                                                                                                                                                                                                                                                                              |
| Phosphorus   | Dissolve 4.260 g $(\text{NH}_4)_2\text{HPO}_4$ in water and dilute to volume.                                                                                                                                                                                                                                                                                                                                       |
| Platinum     | Dissolve 1.000 g Pt in 40 ml of hot aqua regia, evaporate to incipient dryness, add 10 ml $\text{HCl}$ and again evaporate to moist residue. Add 10 ml $\text{HCl}$ and dilute to volume.                                                                                                                                                                                                                           |
| Potassium    | Dissolve 1.9067 g $\text{KCl}$ (or 2.8415 g $\text{KNO}_3$ ) in water and dilute to volume.                                                                                                                                                                                                                                                                                                                         |
| Praseodymium | Dissolve 1.1703 g $\text{Pr}_2\text{O}_3$ in 50 ml of 2 M $\text{HCl}$ ; dilute to volume.                                                                                                                                                                                                                                                                                                                          |
| Rhenium      | Dissolve 1.000 g Re in 10 ml of 8 M $\text{HNO}_3$ in an ice bath until initial reaction subsides, then dilute to volume.                                                                                                                                                                                                                                                                                           |
| Rhodium      | Dissolve 1.000 g Rh by the sealed-tube method described under iridium.                                                                                                                                                                                                                                                                                                                                              |
| Rubidium     | Dissolve 1.4148 g $\text{RbCl}$ in water. Standardize as described under cesium. $\text{Rb}$ (in $\mu\text{g}/\text{ml}$ ) = $(40)(0.320)/(\text{wt of residue})$ .                                                                                                                                                                                                                                                 |
| Ruthenium    | Dissolve 1.317 g $\text{RuO}_2$ in 15 ml of $\text{HCl}$ ; dilute to volume.                                                                                                                                                                                                                                                                                                                                        |
| Samarium     | Dissolve 1.1596 g $\text{Sm}_2\text{O}_3$ in 50 ml of 2 M $\text{HCl}$ ; dilute to volume.                                                                                                                                                                                                                                                                                                                          |
| Scandium     | Dissolve 1.5338 g $\text{Sc}_2\text{O}_3$ in 50 ml of 2 M $\text{HCl}$ ; dilute to volume.                                                                                                                                                                                                                                                                                                                          |

**TABLE 11.48** Standard Stock Solutions (*Continued*)

| Element   | Procedure                                                                                                                                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Selenium  | Dissolve 1.4050 g $\text{SeO}_2$ in water and dilute to volume or dissolve 1.000 g Se in 5 ml of $\text{HNO}_3$ , then dilute to volume.                                                                                                                                                     |
| Silicon   | Fuse 2.1393 g $\text{SiO}_2$ with 4.60 g $\text{Na}_2\text{CO}_3$ , maintaining melt for 15 min in Pt crucible. Cool, dissolve in warm water, and dilute to volume. Solution contains also 2000 $\mu\text{g}/\text{ml}$ sodium.                                                              |
| Silver    | (1) Dissolve 1.5748 g $\text{AgNO}_3$ in water and dilute to volume. (2) Dissolve 1.000 g Ag in 10 ml of $\text{HNO}_3$ ; dilute to volume. Store in amber glass container away from light.                                                                                                  |
| Sodium    | Dissolve 2.5421 g NaCl in water and dilute to volume.                                                                                                                                                                                                                                        |
| Strontium | Dissolve a slurry of 1.6849 g $\text{SrCO}_3$ in 300 ml of water by careful addition of 10 ml of HCl; after release of $\text{CO}_2$ by swirling, dilute to volume.                                                                                                                          |
| Sulfur    | Dissolve 4.122 g $(\text{NH}_4)_2\text{SO}_4$ in water and dilute to volume.                                                                                                                                                                                                                 |
| Tantalum  | Transfer 1.000 g Ta (or 1.2210 g $\text{Ta}_2\text{O}_5$ ) to Pt dish, add 20 ml of HF, and heat gently to complete the dissolution. Cool, add 40 ml of $\text{H}_2\text{SO}_4$ and evaporate to heavy fumes of $\text{SO}_3$ . Cool and dilute to volume with 50% $\text{H}_2\text{SO}_4$ . |
| Tellurium | (1) Dissolve 1.2508 g $\text{TeO}_2$ in 10 ml of HCl; dilute to volume. (2) Dissolve 1.000 g Te in 10 ml of warm HCl with dropwise addition of $\text{HNO}_3$ , then dilute to volume.                                                                                                       |
| Terbium   | Dissolve 1.6692 g of $\text{TbCl}_3$ in water, add 1 ml of HCl, and dilute to volume.                                                                                                                                                                                                        |
| Thallium  | Dissolve 1.3034 g $\text{TlNO}_3$ in water and dilute to volume.                                                                                                                                                                                                                             |
| Thorium   | Dissolve 2.3794 g $\text{Th}(\text{NO}_3)_4 \cdot 4\text{H}_2\text{O}$ in water, add 5 ml $\text{HNO}_3$ , and dilute to volume.                                                                                                                                                             |
| Thulium   | Dissolve 1.142 g $\text{Tm}_2\text{O}_3$ in 50 ml of 2 M HCl; dilute to volume.                                                                                                                                                                                                              |
| Tin       | Dissolve 1.000 g Sn in 15 ml of warm HCl; dilute to volume.                                                                                                                                                                                                                                  |
| Titanium  | Dissolve 1.000 g Ti in 10 ml of $\text{H}_2\text{SO}_4$ with dropwise addition of $\text{HNO}_3$ ; dilute to volume with 5% $\text{H}_2\text{SO}_4$ .                                                                                                                                        |
| Tungsten  | Dissolve 1.7941 g of $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$ in water and dilute to volume.                                                                                                                                                                                       |
| Uranium   | Dissolve 2.1095 g $\text{UO}_2(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ (or 1.7734 g uranyl acetate dihydrate) in water and dilute to volume.                                                                                                                                               |
| Vanadium  | Dissolve 2.2963 g $\text{NH}_4\text{VO}_3$ in 100 ml of water plus 10 ml of $\text{HNO}_3$ ; dilute to volume.                                                                                                                                                                               |
| Ytterbium | Dissolve 1.6147 g $\text{YbCl}_3$ in water and dilute to volume.                                                                                                                                                                                                                             |
| Yttrium   | Dissolve 1.2692 g $\text{Y}_2\text{O}_3$ in 50 ml of 2 M HCl and dilute to volume.                                                                                                                                                                                                           |
| Zinc      | Dissolve 1.000 g Zn in 10 ml of HCl; dilute to volume.                                                                                                                                                                                                                                       |
| Zirconium | Dissolve 3.533 g $\text{ZrOCl}_2 \cdot 8\text{H}_2\text{O}$ in 50 ml of 2 M HCl, and dilute to volume. Solution should be standardized.                                                                                                                                                      |

### 11.7.1 General Reagents, Indicators, and Special Solutions

Unless otherwise stated, the term *g per liter* signifies grams of the formula indicated dissolved in water and made up to a liter of solution.

**Acetic acid**,  $\text{HC}_2\text{H}_3\text{O}_2$ —6N: 350 mL glacial acetic acid per liter.

**Alcohol, amyl**,  $\text{C}_5\text{H}_{11}\text{OH}$ : use as purchased.

**Alcohol, ethyl**,  $\text{C}_2\text{H}_5\text{OH}$ ; 95% alcohol, as purchased.

**Alizarin**, dihydroxyanthraquinone (indicator): dissolve 0.1 g in 100 mL alcohol; pH range yellow 5.5–6.8 red.

**Alizarin yellow R**, sodium *p*-nitrobenzeneazosalicylate (indicator): dissolve 0.1 g in 100 mL water; pH range yellow 10.1–violet 12.1.

**Alizarin yellow GG**, salicyl yellow, sodium *m*-nitrobenzeneazosalicylate (indicator): dissolve 0.1 g in 100 mL 50% alcohol; pH range yellow 10.0–12.0 lilac.

**Alizarin S**, alizarin carmine, sodium alizarin sulfonate (indicator): dissolve 0.1 g in 100 mL water; pH range yellow 3.7–5.2 violet.

**Aluminon** (qualitative test for aluminum). The reagent consists of 0.1% solution of the ammonium salt of aurin tricarboxylic acid. A bright red precipitate, persisting in alkaline solution, indicates aluminum.

**Aluminum chloride**,  $\text{AlCl}_3$ —0.5*N*: 22 g per liter.

**Aluminum nitrate**,  $\text{Al}(\text{NO}_3)_3 \cdot 7.5\text{H}_2\text{O}$ —0.5*N*: 58 g per liter.

**Aluminum sulfate**,  $\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$ —0.5*N*: 55 g per liter.

**Ammonium acetate**,  $\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$ —3*N*: 231 g per liter.

**Ammonium carbonate**,  $(\text{NH}_4)_2\text{CO}_3 \cdot \text{H}_2\text{O}$ —3*N*: 171 g per liter; for the anhydrous salt: 144 g per liter.

**Ammonium chloride**,  $\text{NH}_4\text{Cl}$ —3*N*: 161 g per liter.

**Ammonium hydroxide**,  $\text{NH}_4\text{OH}$ —15*N*: the concentrated solution which contains 28%  $\text{NH}_3$ ; for 6*N*: 400 mL per liter.

**Ammonium molybdate**,  $(\text{NH}_4)_2\text{MoO}_4$ —*N*: dissolve 88.3 g of solid  $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$  in 100 mL 6*N*  $\text{NH}_4\text{OH}$ . Add 240 g of solid  $\text{NH}_4\text{NO}_3$  and dilute to 1 liter. Another method is to take 72 g of  $\text{MoO}_3$ , add 130 mL of water and 75 mL of 15*N*  $\text{NH}_4\text{OH}$ ; stir mechanically until nearly all has dissolved, then add it to a solution of 240 mL concentrated  $\text{HNO}_3$  and 500 mL of water; stir continuously while solutions are being mixed; allow to stand 3 days, filter, and use the clear filtrate.

**Ammonium nitrate**,  $\text{NH}_4\text{NO}_3$ —*N*: 80 g per liter.

**Ammonium oxalate**,  $(\text{NH}_4)_2\text{C}_2\text{O}_4 \cdot \text{H}_2\text{O}$ —0.5*N*: 40 g per liter.

**Ammonium polysulfide** (yellow ammonium sulfide),  $(\text{NH}_4)_2\text{S}_x$ : allow the colorless  $(\text{NH}_4)_2\text{S}$  to stand, or add sulfur.

**Ammonium sulfate**,  $(\text{NH}_4)_2\text{SO}_4$ —0.5*N*: 33 g per liter; saturated: dissolve 780 g of  $(\text{NH}_4)_2\text{SO}_4$  in water and make up to a liter.

**Ammonium sulfide** (colorless),  $(\text{NH}_4)_2\text{S}$ —saturated: pass  $\text{H}_2\text{S}$  through 200 mL of concentrated  $\text{NH}_4\text{OH}$  in the cold until no more gas is dissolved, add 200 mL  $\text{NH}_4\text{OH}$  and dilute with water to a liter; the addition of 15 g of sulfur is sufficient to make the polysulfide.

**Antimony pentachloride**,  $\text{SbCl}_5$ —0.5*N*: 39 g per liter.

**Antimony trichloride**,  $\text{SbCl}_3$ —0.5*N*: 38 g per liter.

**Aqua regia**: mix 3 parts of concentrated  $\text{HCl}$  and 1 part of concentrated  $\text{HNO}_3$  just before ready to use.

**Arsenic acid**,  $\text{H}_3\text{AsO}_4 \cdot 0.5\text{H}_2\text{O}$ —0.5*N* ( $= \frac{1}{2}\text{H}_3\text{AsO}_4 \div 5$ ): 15 g per liter.

**Arsenous oxide**,  $\text{As}_2\text{O}_3$ —0.25*N*: 8 g per liter for saturation.

**Aurichloric acid**,  $\text{HAuCl}_4 \cdot 3\text{H}_2\text{O}$ : dissolve in ten parts of water.

**Aurin**, *see* rosolic acid.

**Azolitmin solution** (indicator); make up a 1% solution of azolitmin by boiling in water for 5 minutes; it may be necessary to add a small amount of  $\text{NaOH}$  to make the solution neutral; pH range red 4.5–8.3 blue.

**Bang's reagent** (for glucose estimation): dissolve 100 g of  $\text{K}_2\text{CO}_3$ , 66 g of KCl, and 160 of  $\text{KHCO}_3$  in the order given in about 700 mL of water at  $30^\circ\text{C}$ . Add 4.4 g of copper sulfate and dilute to 1 liter after the  $\text{CO}_2$  is evolved. This solution should be shaken only in such a manner as not to allow the entry of air. After 24 hours 300 mL diluted to a liter with saturated KCl solution, shaken gently and used after 24 hours; 50 mL  $\equiv$  10 mg glucose.

**Barfoed's reagent** (test for glucose): dissolve 66 g of cupric acetate and 10 mL of glacial acetic acid in water and dilute to 1 liter.

**Barium chloride**,  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$ —0.5*N*: 61 g per liter.

**Barium hydroxide**,  $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ —0.2*N*: 32 g per liter for saturation.

**Barium nitrate**,  $\text{Ba}(\text{NO}_3)_2$ —0.5*N*: 65 g per liter.

**Baudisch's reagent**: see cupferron.

**Benedict's qualitative reagent** (for glucose): dissolve 173 g of sodium citrate and 100 g of anhydrous sodium carbonate in about 600 mL of water, and dilute to 850 mL; dissolve 17.3 g of  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  in 100 mL of water and dilute to 150 mL; this solution is added to the citrate-carbonate solution with constant stirring. See also the quantitative reagent below.

**Benedict's quantitative reagent** (sugar in urine): This solution contains 18 g copper sulfate, 100 g of anhydrous sodium carbonate, 200 g of potassium citrate, 125 g of potassium thiocyanate, and 0.25 g of potassium ferrocyanide per liter; 1 mL of this solution  $\equiv$  0.002 g sugar.

**Benzidine hydrochloride solution** (for sulfate determination): mix 6.7 g of benzidine [ $\text{C}_{12}\text{H}_8(\text{NH}_2)_2$ ] or 8.0 g of the hydrochloride [ $\text{C}_{12}\text{H}_8(\text{NH}_2)_2 \cdot 2\text{HCl}$ ] into a paste with 20 mL of water; add 20 mL of HCl (sp. gr. 1.12) and dilute the mixture to 1 liter with water; each mL of this solution is equivalent to 0.00357 g  $\text{H}_2\text{SO}_4$ .

**Benzopurpurine 4B** (indicator): dissolve 0.1 g in 100 mL water; pH range blue-violet 1.3–4.0 red.

**Benzoyl auramine** (indicator): dissolve 0.25 g in 100 mL methyl alcohol; pH range violet 5.0–5.6 pale yellow. Since this compound is not stable in aqueous solution, hydrolyzing slowly in neutral medium, more rapidly in alkaline, and still more rapidly in acid solution, the indicator should not be added until one is ready to titrate. The acid quinoid form of the compound is dichroic, showing a red-violet in thick layers and blue in thin. At a pH of 5.4 the indicator appears a neutral gray color by daylight or a pale red under tungsten light. The change to yellow is easily recognized in either case. Cf. Scanlan and Reid, *Ind. Eng. Chem., Anal. Ed.* 7:125 (1935).

**Bertrand's reagents** (glucose estimation): (a) 40 g of copper sulfate diluted to 1 liter; (b) rochelle salt 200 g, NaOH 150 g, and sufficient water to make 1 liter; (c) ferric sulfate 50 g,  $\text{H}_2\text{SO}_4$  200 g, and sufficient water to make 1 liter; (d)  $\text{KMnO}_4$  5 g and sufficient water to make 1 liter.

**Bial's reagent** (for pentoses): dissolve 1 g of orcinol in 500 mL of 30% HCl to which 30 drops of a 10% ferric chloride solution have been added.

**Bismuth chloride**,  $\text{BiCl}_3$ —0.5*N*: 52 g per liter, using 1:5 HCl in place of water.

**Bismuth nitrate**,  $\text{Bi}(\text{N}_2\text{O}_5)_3 \cdot 5\text{H}_2\text{O}$ —0.25*N*: 40 g per liter, using 1:5  $\text{HNO}_3$  in place of water.

**Bismuth standard solution** (quantitative color test for Bi): dissolve 1 g of bismuth in a mixture of 3 mL of concentrated  $\text{HNO}_3$  and 2.8 mL of  $\text{H}_2\text{O}$  and make up to 100 mL with glycerol. Also dissolve 5 g of KI in 5 mL of water and make up to 100 mL with glycerol. The two solutions are used together in the colorimetric estimation of Bi.

**Boutron-Boudet solution**: see soap solution.

**Bromchlorophenol blue**, dibromodichlorophenol-sulfonphthalein (indicator): dissolve 0.1 g in 8.6 mL 0.02 *N* NaOH and dilute with water to 250 mL; pH range yellow 3.2–4.8 blue.

**Bromcresol green**, tetrabromo-*m*-cresol-sulfonphthalein (indicator): dissolve 0.1 g in 7.15 mL 0.02 *N* NaOH and dilute with water to 250 mL; or, 0.1 g in 100 mL 20% alcohol; pH range yellow 4.0–5.6 blue.

**Bromcresol purple**, dibromo-*o*-cresol-sulfonphthalein (indicator): dissolve 0.1 g in 9.5 mL 0.02 *N* NaOH and dilute with water to 250 mL; or, 0.1 g in 100 mL 20% alcohol; pH range yellow 5.2–6.8 purple.

**Bromine water**, saturated solution: to 400 mL water add 20 mL of bromine; use a glass stopper coated with petrolatum.

**Bromphenol blue**, tetrabromophenol-sulfonphthalein (indicator): dissolve 0.1 g in 7.45 mL 0.02 *N* NaOH and dilute with water to 250 mL; or, 0.1 g in 100 mL 20% alcohol; pH range yellow 3.6–4.6 violet-blue.

**Bromphenol red**, dibromophenol-sulfonphthalein (indicator): dissolve 0.1 g in 9.75 mL 0.02 *N* NaOH and dilute with water to 250 mL; pH range yellow 5.2–7.0 red.

**Bromthymol blue**, dibromothymol-sulfonphthalein (indicator): dissolve 0.1 g in 8.0 mL 0.02 *N* NaOH and dilute with water to 250 mL; or, 0.1 g in 100 mL of 20% alcohol; pH range yellow 6.0–7.6 blue.

**Brucke's reagent** (protein precipitant): dissolve 50 g of KI in 500 mL of water, saturate with HgI<sub>2</sub> (about 120 g), and dilute to 1 liter.

**Cadmium chloride**, CdCl<sub>2</sub>—0.5*N*: 46 g per liter.

**Cadmium nitrate**, Cd(NO<sub>3</sub>)<sub>2</sub> · 4H<sub>2</sub>O—0.5*N*: 77 g per liter.

**Cadmium sulfate**, CdSO<sub>4</sub> · 4H<sub>2</sub>O—0.5*N*: 70 g per liter.

**Calcium chloride**, CaCl<sub>2</sub> · 6H<sub>2</sub>O—0.5*N*: 55 g per liter.

**Calcium hydroxide**, Ca(OH)<sub>2</sub>—0.04*N*: 10 g per liter for saturation.

**Calcium nitrate**, Ca(NO<sub>3</sub>)<sub>2</sub> · 4H<sub>2</sub>O—0.5*N*: 59 g per liter.

**Calcium sulfate**, CaSO<sub>4</sub> · 2H<sub>2</sub>O—0.03*N*: mechanically stir 10 g in a liter of water for 3 hours; decant and use the clear liquid.

**Carbon disulfide**, CS<sub>2</sub>: commercial grade which is colorless.

**Chloride reagent**: dissolve 1.7 g of AgNO<sub>3</sub> and 25 g KNO<sub>3</sub> in water, add 17 mL of concentrated NH<sub>4</sub>OH and make up to 1 liter with water.

**Chlorine water**, saturated solution: pass chlorine gas into small amounts of water as needed; solutions deteriorate on standing.

**Chloroform**, CHCl<sub>3</sub>: commercial grade.

**Chloroplatinic acid**, H<sub>2</sub>PtCl<sub>6</sub> · 6H<sub>2</sub>O—10% solution: dissolve 1 g in 9 mL of water; keep in a dropping bottle.

**Chlorphenol red**, dichlorophenol-sulfonphthalein (indicator): dissolve 0.1 g in 11.8 mL 0.02 *N* NaOH and dilute with water to 250 mL; or, 0.1 g in 100 mL 20% alcohol; pH range yellow 5.2–6.6 red.

**Chromic chloride**, CrCl<sub>3</sub>—0.5*N*: 26 g per liter.

**Chromic nitrate**, Cr(NO<sub>3</sub>)<sub>3</sub>—0.5*N*: 40 g per liter.

**Chromic sulfate**, Cr<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> · 18H<sub>2</sub>O—0.5*N*: 60 g per liter.

**Cobaltous nitrate**, Co(NO<sub>3</sub>)<sub>2</sub> · 6H<sub>2</sub>O—0.5*N*: 73 g per liter.

**Cobaltous sulfate**,  $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$ —0.5*N*: 70 g per liter.

**Cochineal** (indicator): triturate 1 g with 75 mL alcohol and 75 mL water, let stand for two days and filter; pH range red 4.8–6.2 violet.

**Congo red**, sodium tetrazodiphenyl-naphthionate (indicator): dissolve 0.1 g in 100 mL water; pH range blue 3.0–5.2 red.

**Corallin** (indicator): *see* rosolic acid.

**Cresol red**, *o*-cresol-sulfonphthalein (indicator): dissolve 0.1 g in 13.1 mL 0.02*N* NaOH and dilute with water to 250 mL; or, 0.1 g in 100 mL 20% alcohol; pH range yellow 7.2–8.8 red.

***o*-Cresolphthalein** (indicator): dissolve 0.1 g in 250 mL alcohol; pH range colorless 8.2–10.4 red.

**Cupferron** (iron analysis): dissolve 6 g of ammonium nitrosophenyl-hydroxylamine (cupferron) in water and dilute to 100 mL. This solution is stable for about one week if protected from light.

**Cupric chloride**,  $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ —0.5*N*: 43 g per liter.

**Cupric nitrate**,  $\text{Cu}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ —0.5*N*: 74 g per liter.

**Cupric sulfate**,  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ —0.5*N*: 62 g per liter.

**Cuprous chloride**,  $\text{CuCl}$ —0.5*N*: 50 g per liter, using 1:5 HCl in place of water.

**Cuprous chloride**, acid (for gas analysis, absorption of CO): cover the bottom of a 2-liter bottle with a layer of copper oxide  $\frac{3}{8}$  inch deep, and place a bundle of copper wire an inch thick in the bottle so that it extends from the top to the bottom. Fill the bottle with HCl (sp. gr. 1.10). The bottle is shaken occasionally, and when the solution is colorless or nearly so, it is poured into half-liter bottles containing copper wire. The large bottle may be filled with hydrochloric acid, and by adding the oxide or wire when either is exhausted, a constant supply of the reagent is available.

**Cuprous chloride, ammoniacal**: this solution is used for the same purpose and is made in the same manner as the acid cuprous chloride above, except that the acid solution is treated with ammonia until a faint odor of ammonia is perceptible. Copper wire should be kept with the solution as in the acid reagent.

**Curcumin** (indicator): prepare a saturated aqueous solution; pH range yellow 6.0–8.0 brownish red.

**Dibromophenol-tetrabromophenol-sulfonphthalein** (indicator): dissolve 0.1 g in 1.21 mL 0.1*N* NaOH and dilute with water to 250 mL; pH range yellow 5.6–7.2 purple.

**Dimethyl glyoxime**,  $(\text{CH}_3\text{CNOH})_2$ —0.01*N*: 6 g in 500 mL of 95% alcohol.

**2,4-Dinitrophenol** (indicator): dissolve 0.1 g in a few mL alcohol, then dilute with water to 100 mL; pH range colorless 2.6–4.0 yellow.

**2,5-Dinitrophenol** (indicator): dissolve 0.1 g in 20 mL alcohol, then dilute with water to 100 mL; pH range colorless 4–5.8 yellow.

**2,6-Dinitrophenol** (indicator): dissolve 0.1 g in a few mL alcohol, then dilute with water to 100 mL; pH range colorless 2.4–4.0 yellow.

**Esbach's reagent** (estimation of proteins): dissolve 10 g of picric acid and 20 g of citric acid in water and dilute to 1 liter.

**Eschka's mixture** (sulfur in coal): mix 2 parts of porous calcined MgO with 1 part of anhydrous  $\text{Na}_2\text{CO}_3$ ; not a solution but a dry mixture.

**Ether**,  $(\text{C}_2\text{H}_5)_2\text{O}$ —use commercial grade.

***p*-Ethoxychrysoidine**, *p*-ethoxybenzeneazo-*m*-phenylenediamine (indicator): dissolve 0.1 g of the base in 100 mL 90% alcohol; or, 0.1 g of the hydrochloride salt in 100 mL water; pH range red 3.5–5.5 yellow.

**Ethyl bis-(2,4-dinitrophenyl) acetate** (indicator): the stock solution is prepared by saturating a solution containing equal volumes of alcohol and acetone with the indicator; pH range colorless 7.4–9.1 deep blue. This compound is available commercially. The preparation of this compound is described by Fehnel and Amstutz, *Ind. Eng. Chem., Anal. Ed.* **16**:53 (1944), and by von Richter, *Ber.* **21**:2470 (1888), who recommended it for the titration of orange- and red-colored solutions or dark oils in which the endpoint of phenol-phthalein is not easily visible. The indicator is an orange solid which after crystallization from benzene gives pale yellow crystals melting at 150–153.5°C, uncorrected.

**Fehling's solution** (sugar detection and estimation): (a) Copper sulfate solution: dissolve 34.639 g of  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  in water and dilute to 500 mL. (b) Alkaline tartrate solution: dissolve 173 g of rochelle salts ( $\text{KNaC}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$ ) and 125 g of KOH in water and dilute to 500 mL. Equal volumes of the two solutions are mixed just prior to use. The Methods of the Assoc. of Official Agricultural Chemists give 50 g of NaOH in place of the 125 g KOH.

**Ferric chloride**,  $\text{FeCl}_3$ —0.5*N*: 27 g per liter.

**Ferric nitrate**,  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$ —0.5*N*: 67 g per liter.

**Ferrous ammonium sulfate**, Mohr's salt,  $\text{FeSO}_4 \cdot (\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ —0.5*N*: 196 g per liter.

**Ferrous sulfate**,  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ —0.5*N*: 80 g per liter; add a few drops of  $\text{H}_2\text{SO}_4$ .

**Folin's mixture** (for uric acid): dissolve 500 g of ammonium sulfate, 5 g of uranium acetate, and 6 mL of glacial acetic acid, in 650 mL of water. The volume is about a liter.

**Formal or Formalin**: use the commercial 40% solution of formaldehyde.

**Froehde's reagent** (gives characteristic colorations with certain alkaloids and glycosides): dissolve 0.01 g of sodium molybdate in 1 mL of concentrated  $\text{H}_2\text{SO}_4$ ; use only a freshly prepared solution.

**Gallein** (indicator): dissolve 0.1 g in 100 mL alcohol; pH range light brown-yellow 3.8–6.6 rose.

**Glyoxylic acid solution** (protein detection): cover 10 g of magnesium powder with water and slowly add 250 mL of a saturated oxalic solution, keeping the mixture cool; filter off the magnesium oxalate, acidify the filtrate with acetic acid and make up to a liter with water.

**Guaiacum tincture**: dissolve 1 g of guaiacum in 100 mL of alcohol.

**Gunzberg's reagent** (detection of HCl in gastric juice): dissolve 4 g of phloroglucinol and 2 g of vanillin in 100 mL of absolute alcohol; use only a freshly prepared solution.

**Hager's reagent** (for alkaloids): this reagent is a saturated solution of picric acid in water.

**Hanus solution** (for determination of iodine number): dissolve 13.2 g of iodine in a liter of glacial acetic acid that will not reduce chromic acid; add sufficient bromine to double the halogen content determined by titration (3 mL is about the right amount). The iodine may be dissolved with the aid of heat, but the solution must be cold when the bromine is added.

**Hematoxylin** (indicator): dissolve 0.5 g in 100 mL alcohol; pH range yellow 5.0–6.0.

**Heptamethoxy red**, 2,4,6,2',4',2'',4''-heptamethoxytriphenyl carbinol (indicator): dissolve 0.1 g in 100 mL alcohol; pH range red 5.0–7.0 colorless.

**Hydriodic acid**, HI—0.5*N*: 64 g per liter.

**Hydrobromic acid**, HBr—0.5*N*: 40 g per liter.

**Hydrochloric acid**, HCl—5*N*: 182 g per liter; sp. gr. 1.084.

**Hydrofluoric acid**,  $\text{H}_2\text{F}_2$ —48% solution: use as purchased, and keep in the special container.

**Hydrogen peroxide**,  $\text{H}_2\text{O}_2$ —3% solution: use as purchased.

**Hydrogen sulfide**,  $\text{H}_2\text{S}$ : prepare a saturated aqueous solution.

**Indicator solutions:** a number of indicator solutions are listed in this section under the names of the indicators; e.g., alizarin, aurin, azolitmin, et al., which follow alphabetically. *See also* various index entries.

**Indigo carmine**, sodium indigodisulfonate (indicator): dissolve 0.25 g in 100 mL 50% alcohol; pH range blue 11.6–14.0 yellow.

**Indo-oxine**, 5,8-quinolinequinone-8-hydroxy-5-quinoyl-5-imide (indicator): dissolve 0.05 g in 100 mL alcohol; pH range red 6.0–8.0 blue. Cf. Berg and Becker, *Z. Anal. Chem.* **119**:81 (1940).

**Iodeosin**, tetraiodofluorescein (indicator): dissolve 0.1 g in 100 mL ether saturated with water; pH range yellow 0—about 4 rose-red; *see also* under methyl orange.

**Iodic acid**,  $\text{HIO}_3$ —0.5N ( $\text{HIO}_3/12$ ): 15 g per liter.

**Iodine:** *see* tincture of iodine.

**Lacmoid** (indicator): dissolve 0.5 g in 100 mL alcohol; pH range red 4.4–6.2 blue.

**Lead acetate**,  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 3\text{H}_2\text{O}$ —0.5N: 95 g per liter.

**Lead chloride**,  $\text{PbCl}_2$ —saturated solution is 1/7N.

**Lead nitrate**,  $\text{Pb}(\text{NO}_3)_2$ —0.5N: 83 g per liter.

**Lime water:** *see* calcium hydroxide.

**Litmus** (indicator): powder the litmus and make up a 2% solution in water by boiling for 5 minutes; pH range red 4.5–8.3 blue.

**Magnesia mixture:** 100 g of  $\text{MgSO}_4$ , 200 g of  $\text{NH}_4\text{Cl}$ , 400 mL of  $\text{NH}_4\text{Cl}$ , 800 mL of water; each mL  $\equiv$  0.01 g phosphorus (P).

**Magnesium chloride**,  $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ —0.5N: 50 g per liter.

**Magnesium nitrate**,  $\text{Mg}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ —0.5N: 64 g per liter.

**Magnesium sulfate**, epsom salts,  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ —0.5N: 62 g per liter; saturated solution dissolve 600 g of the salt in water and dilute to 1 liter.

**Manganous chloride**,  $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$ —0.5N: 50 g per liter.

**Manganous nitrate**,  $\text{Mn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ —0.5N: 72 g per liter.

**Manganous sulfate**,  $\text{MnSO}_4 \cdot 7\text{H}_2\text{O}$ —0.5N: 69 g per liter.

**Marme's reagent** (gives yellowish-white precipitate with salts of alkaloids): saturate a boiling solution of 4 parts of KI in 12 parts of water with  $\text{CdI}_2$ ; then add an equal volume of cold saturated KI solution.

**Marquis reagent** (gives a purple-red coloration, then violet, then blue with morphine, codeine, dionine, and heroine): mix 3 mL of concentrated  $\text{H}_2\text{SO}_4$  with 3 drops of a 35% formaldehyde solution.

**Mayer's reagent** (gives white precipitate with most alkaloids in a slightly acid solution): dissolve 13.55 g of  $\text{HgCl}_2$  and 50 g of KI in a liter of water.

**Mercuric chloride**,  $\text{HgCl}_2$ —0.5N: 68 g per liter.

**Mercuric nitrate**,  $\text{Hg}(\text{NO}_3)_2$ —0.5N: 81 g per liter.

**Mercuric sulfate**,  $\text{HgSO}_4$ —0.5N: 74 g per liter.

**Mercurous nitrate**,  $\text{HgNO}_3$ : mix 1 part of  $\text{HgNO}_3$ , 20 parts of  $\text{H}_2\text{O}$ , and 1 part of  $\text{HNO}_3$ .

**Metacresol purple**, *m*-cresol-sulfonphthalein (indicator): dissolve 0.1 g in 13.6 mL 0.02N NaOH and dilute with water to 250 mL; acid pH range red 0.5–2.5 yellow, alkaline pH range yellow 7.4–9.0 purple.

**Metanil yellow**, diphenylaminoazo-*m*-benzene sulfonic acid (indicator): dissolve 0.25 g in 100 mL alcohol; pH range red 1.2–2.3 yellow.

**Methyl green**, hexamethylpararosanine hydroxymethylate (component of mixed indicator): dissolve 0.1 g in 100 mL alcohol; when used with equal parts of hexamethoxytriphenyl carbinol gives color change from violet to green at a titration exponent (pI) of 4.0.

**Methyl orange**, orange III, tropeolin D, sodium *p*-dimethylaminoazobenzenesulfonate (indicator): dissolve 0.1 g in 100 mL water; pH range red 3.0–4.4 orange-yellow. If during a titration where methyl yellow is being used a precipitate forms which tends to remove the indicator from the aqueous phase, methyl orange will be found to be a more suitable indicator. This occurs, for example, in titrations of soaps with acids. The fatty acids, liberated by the titration, extract the methyl yellow so that the endpoint cannot be perceived. Likewise methyl orange is more suitable for titrations in the presence of immiscible organic solvents such as carbon tetrachloride or ether used in the extraction of alkaloids for analysis. Iodeosin (*q.v.*) has also been proposed as an indicator for such cases. Cf. Mylius and Foerster, *Ber.* **24**:1482 (1891); *Z. Anal. Chem.* **31**:240 (1892).

**Methyl red**, *p*-dimethylaminoazobenzene-*o*'-carboxylic acid (indicator): dissolve 0.1 g in 18.6 mL of 0.02N NaOH and dilute with water to 250 mL; or, 0.1 g in 60% alcohol; pH range red 4.4–6.2 yellow.

**Methyl violet** (indicator): dissolve 0.25 g in 100 mL water, pH range blue 1.5–3.2 violet.

**Methyl yellow**, *p*-dimethylaminoazobenzene, benzeneazodimethylaniline (indicator): dissolve 0.1 g in 200 mL alcohol; pH range red 2.9–4.0 yellow. The color change from yellow to orange can be perceived somewhat more sharply than the change of methyl orange from orange to rose, so that methyl yellow seems to deserve preference in many cases. *See also* under methyl orange.

**Methylene blue**, *N,N,N',N'*-tetramethylthionine (component of mixed indicator): dissolve 0.1 g in 100 mL alcohol; when used with equal part of methyl yellow gives color change from blue-violet to green at a titration exponent (pI) of 3.25; when used with equal part of 0.2% methyl red in alcohol gives color change from red-violet to green at a titration exponent (pI) of 5.4; when used with an equal part of neutral red gives color change from violet-blue to green at a titration exponent (pI) of 7.0.

**Millon's reagent** (gives a red precipitate with certain proteins and with various phenols): dissolve 1 part of mercury in 1 part of  $\text{HNO}_3$  (sp. gr. 1.40) with gentle heating, then add 2 parts of water; a few crystals of  $\text{KNO}_3$  help to maintain the strength of the reagent.

**Mohr's salt**: *see* ferrous ammonium sulfate.

**$\alpha$ -Naphthol solution**: dissolve 144 g of  $\alpha$ -naphthol in enough alcohol to make a liter of solution.

**$\alpha$ -Naphtholbenzein** (indicator): dissolve 0.1 g in 100 mL 70% alcohol; pH range colorless 9.0–11.0 blue.

**$\alpha$ -Naphtholphthalein** (indicator): dissolve 0.1 g in 50 mL alcohol and dilute with water to 100 mL; pH range pale yellow-red 7.3–8.7 green.

**Nessler's reagent** (for free ammonia): dissolve 50 g of KI in the least possible amount of cold water; add a saturated solution of  $\text{HgCl}_2$  until a very slight excess is indicated; add 400 mL of a 50% solution of KOH; allow to settle, make up to a liter with water, and decant.

**Neutral red**, toluylene red, dimethyldiaminophenazine chloride, aminodimethylaminotoluphenazine hydrochloride (indicator): dissolve 0.1 g in 60 mL alcohol and dilute with water to 100 mL; pH range red 6.8–8.0 yellow-orange.

**Nickel chloride**,  $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$ —0.5N: 59 g per liter.

**Nickel nitrate**,  $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ —0.5N: 73 g per liter.

**Nickel sulfate**,  $\text{NiSO}_4 \cdot 6\text{H}_2\text{O}$ —0.5N: 66 g per liter.

**Nitramine**, picrylmethylnitramine, 2,4,6-trinitrophenylmethyl nitramine (indicator): dissolve 0.1 g in 60 mL alcohol and dilute with water to 100 mL; pH range colorless 10.8–13.0 red-brown; the solution should be kept in the dark as nitramine is unstable; on boiling with alkali it decomposes quickly. Fresh solutions should be prepared every few months.

**Nitric acid**,  $\text{HNO}_3$ —5N: 315 g per liter; sp. gr. 1.165.

**Nitrohydrochloric acid**: see aqua regia.

**p-Nitrophenol** (indicator): dissolve 0.2 g in 100 mL water; pH range colorless at about 5–7 yellow.

**Nitroso- $\beta$ -naphthol**,  $\text{HOC}_{10}\text{H}_6\text{NO}$ —saturated solution: saturate 100 mL of 50% acetic acid with the solid.

**Nylander's solution** (detection of glucose): dissolve 40 g of rochelle salt and 20 g of bismuth subnitrate in 1000 mL of an 8% NaOH solution.

**Obermayer's reagent** (detection of indoxyl in urine): dissolve 4 g of  $\text{FeCl}_3$  in a liter of concentrated HCl.

**Orange III** (indicator): see under methyl orange.

**Oxalic acid**,  $\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$ : dissolve in ten parts of water.

**Pavy's solution** (estimation of glucose): mix 120 mL of Fehling's solution and 300 mL of ammonium hydroxide (sp. gr. 0.88), and dilute to a liter with water.

**Perchloric acid**,  $\text{HClO}_4$ —60%: use as purchased.

**Phenol red**, phenol-sulfonphthalein (indicator): dissolve 0.1 g in 14.20 mL 0.02N NaOH and dilute with water to 250 mL; or, 0.1 g in 100 mL 20% alcohol; pH range yellow 6.8–8.0 red.

**Phenol solution**: dissolve 20 g of phenol (carbolic acid) in a liter of water.

**Phenol sulfonic acid** (determination of nitrogen as nitrate; water analysis for nitrate): dissolve 25 g pure, white phenol in 150 mL of pure concentrated  $\text{H}_2\text{SO}_4$ , add 75 mL of fuming  $\text{H}_2\text{SO}_4$  (15%  $\text{SO}_3$ ), stir well and heat for two hours at 100°C.

**Phenolphthalein** (indicator): dissolve 1 g in 60 mL of alcohol and dilute with water to 100 mL; pH range colorless 8.2–10.0 red.

**Phosphoric acid**, *ortho*,  $\text{H}_3\text{PO}_4$ —0.5N: 16 g per liter.

**Poirrer blue C4B** (indicator): dissolve 0.2 g in 100 mL water; pH range blue 11.0–13.0 red.

**Potassium acid antimonate**,  $\text{KH}_2\text{SbO}_4$ —0.1N: boil 23 g of the salt with 950 mL of water for 5 minutes, cool rapidly and add 35 mL of 6N KOH; allow to stand for one day, filter dilute filtrate to a liter.

**Potassium arsenate**,  $\text{K}_3\text{AsO}_4$ —0.5N ( $\text{K}_3\text{AsO}_4/10$ ): 26 g per liter.

**Potassium arsenite**,  $\text{KAsO}_2$ —0.5N ( $\text{KAsO}_2/6$ ): 24 g per liter.

**Potassium bromate**,  $\text{KBrO}_3$ —0.5N ( $\text{KBrO}_3/12$ ): 14 g per liter.

**Potassium bromide**,  $\text{KBr}$ —0.5N: 60 g per liter.

**Potassium carbonate**,  $\text{K}_2\text{CO}_3$ —3*N*: 207 g per liter.

**Potassium chloride**,  $\text{KCl}$ —0.5*N*: 37 g per liter.

**Potassium chromate**,  $\text{K}_2\text{CrO}_4$ —0.5*N*: 49 g per liter.

**Potassium cyanide**,  $\text{KCN}$ —0.5*N*: 33 g per liter.

**Potassium dichromate**,  $\text{K}_2\text{Cr}_2\text{O}_7$ —0.5*N* ( $\text{K}_2\text{Cr}_2\text{O}_7/8$ ): 38 g per liter.

**Potassium ferricyanide**,  $\text{K}_3\text{Fe}(\text{CN})_6$ —0.5*N*: 55 g per liter.

**Potassium ferrocyanide**,  $\text{K}_4\text{Fe}(\text{CN})_6 \cdot 3\text{H}_2\text{O}$ —0.5*N*: 53 g per liter.

**Potassium hydroxide**,  $\text{KOH}$ —5*N*: 312 g per liter.

**Potassium iodate**,  $\text{KIO}_3$ —0.5*N* ( $\text{KIO}_3/12$ ): 18 g per liter.

**Potassium iodide**,  $\text{KI}$ —0.5*N*: 83 g per liter.

**Potassium nitrate**,  $\text{KNO}_3$ —0.5*N*: 50 g per liter.

**Potassium nitrate**,  $\text{KNO}_2$ —6*N*: 510 g per liter.

**Potassium permanganate**,  $\text{KMnO}_4$ —0.5*N* ( $\text{KMnO}_4/10$ ): 16 g per liter.

**Potassium pyrogallate** (oxygen in gas analysis): weigh out 5 g of pyrogallol (pyrogallic acid), and pour upon it 100 mL of a  $\text{KOH}$  solution. If the gas contains less than 28% of oxygen, the  $\text{KOH}$  solution should be 500 g  $\text{KOH}$  in a liter of water; if there is more than 28% of oxygen in the gas, the  $\text{KOH}$  solution should be 120 g of  $\text{KOH}$  in 100 mL of water.

**Potassium sulfate**,  $\text{K}_2\text{SO}_4$ —0.5*N*: 44 g per liter.

**Potassium thiocyanate**,  $\text{KCNS}$ —0.5*N*: 49 g per liter.

**Precipitating reagent** (for group II, anions): dissolve 61 g of  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$  and 52 g of  $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$  in water and dilute to 1 liter. If the solution becomes turbid, filter and use filtrate.

**Quinaldine red** (indicator): dissolve 0.1 g in 100 mL alcohol; pH range colorless 1.4–3.2 red.

**Quinoline blue**, cyanin (indicator): dissolve 1 g in 100 mL alcohol; pH range colorless 6.6–8.6 blue.

**Rosolic acid**, aurin, corallin, corallinphthalein, 4,4'-dihydroxy-fuchsone, 4,4'-dihydroxy-3-methyl-fuchsone (indicator): dissolve 0.5 g in 50 mL alcohol and dilute with water to 100 mL.

**Salicyl yellow** (indicator): *see* alizarin yellow GG.

**Scheibler's reagent** (precipitates alkaloids, albumoses and peptones): dissolve sodium tungstate in boiling water containing half its weight of phosphoric acid (sp. gr. 1.13); on evaporation of this solution, crystals of phosphotungstic acid are obtained. A 10% solution of phosphotungstic acid in water constitutes the reagent.

**Schweitzer's reagent** (dissolves cotton, linen, and silk, but not wool); add  $\text{NH}_4\text{Cl}$  and  $\text{NaOH}$  to a solution of copper sulfate. The blue precipitate is filtered off, washed, pressed, and dissolved in ammonia (sp. gr. 0.92).

**Silver nitrate**,  $\text{AgNO}_3$ —0.25*N*: 43 g per liter.

**Silver sulfate**,  $\text{Ag}_2\text{SO}_4$ —*N*/13 (saturated solution): stir mechanically 10 g of the salt in a liter of water for 3 hours; decant and use the clear liquid.

**Soap solution** (for hardness in water): (*a*) *Clark's or A.P.H.A. Stand. Methods*—prepare stock solution of 100 g of pure powdered castile soap in a liter of 80% ethyl alcohol; allow to stand over night and decant. Titrate against  $\text{CaCl}_2$  solution (0.5 g  $\text{CaCO}_3$  dissolved in a concentrated  $\text{HCl}$ , neutralized with  $\text{NH}_4\text{OH}$  to slight alkalinity using litmus as the indicator, make up to 500 mL; 1 mL of this solution is equivalent to 1 mg  $\text{CaCO}_3$ ) and dilute with 80% alcohol until 1 mL of the resulting solution is equivalent to 1 mL of the standard  $\text{CaCl}_2$  making due allowance

for the lather factor (the lather factor is that amount of standard soap solution required to produce a permanent lather in a 50-mL portion of distilled water). One milliliter of this solution after subtracting the lather factor is equivalent to 1 mg of  $\text{CaCO}_3$ . (b) *Boutron-Boudet*—dissolve 100 g of pure castile soap in about 2500 mL of 56% ethyl alcohol and adjust so that 2.4 mL will give a permanent lather with 40 mL of a solution containing 0.59 g  $\text{Ba}(\text{NO}_3)_2$  per liter of water; 2.4 mL of this solution is equivalent to 22 French degrees or 220 parts per million of hardness (as  $\text{CaCO}_3$ ) on a 40-mL sample of water.

**Sodium acetate**,  $\text{NaC}_2\text{H}_3\text{O}_2 \cdot 3\text{H}_2\text{O}$ : dissolve 1 part of the salt in 10 parts of water.

**Sodium acetate, acid**: dissolve 100 g of sodium acetate and 30 mL of glacial acetic acid in water and dilute to 1 liter.

**Sodium bismuthate** (oxidation of manganese): heat 20 parts of  $\text{NaOH}$  nearly to redness in an iron or nickel crucible, and add slowly 10 parts of basic bismuth nitrate which has been previously dried. Add 2 parts of sodium peroxide, and pour the brownish-yellow fused mass on an iron plate to cool. When cold break up in a mortar, extract with water, and collect on an asbestos filter.

**Sodium carbonate**,  $\text{Na}_2\text{CO}_3 \cdot 3\text{H}_2\text{O}$ : 159 g per liter; one part  $\text{Na}_2\text{CO}_3$ , or 2.7 parts of the crystalline  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$  in 5 parts of water.

**Sodium chloride**,  $\text{NaCl}$ —0.5N: 29 g per liter.

**Sodium chloroplatinite**,  $\text{Na}_2\text{PtCl}_4$ : dissolve 1 part of the salt in 12 parts of water.

**Sodium cobaltinitrite**,  $\text{Na}_2\text{Co}(\text{NO}_2)_6$ —0.3N: dissolve 230 g of  $\text{NaNO}_2$  in 500 mL of water, add 160 mL of 6N acetic acid and 35 g of  $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ . Allow to stand one day, filter, and dilute the filtrate to a liter.

**Sodium hydrogen phosphate**,  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ —0.5N: 60 g liter.

**Sodium hydroxide**,  $\text{NaOH}$ —5N: 220 g per liter.

**Sodium hydroxide, alcoholic**: dissolve 20 g of  $\text{NaOH}$  in alcohol and dilute to 1 liter with alcohol.

**Sodium hypobromite**: dissolve 100 g of  $\text{NaOH}$  in 250 mL of water and add 25 mL of bromine.

**Sodium nitrate**,  $\text{NaNO}_3$ —0.5N: 43 g per liter.

**Sodium nitroprusside** (for sulfur detection): dissolve about 1 g of sodium nitroprusside in 10 mL of water; as the solution deteriorates on standing, only freshly prepared solutions should be used. This compound is also called sodium nitroferrocyanide and has the formula  $\text{Na}_2\text{Fe}(\text{NO})(\text{CN})_5 \cdot 2\text{H}_2\text{O}$ .

**Sodium polysulfide**,  $\text{Na}_2\text{S}_x$ : dissolve 480 g of  $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$  in 500 mL of water, add 40 g of  $\text{NaOH}$  and 18 g of sulfur, stir mechanically and dilute to 1 liter with water.

**Sodium sulfate**,  $\text{Na}_2\text{SO}_4$ —0.5N: 35 g per liter.

**Sodium sulfide**,  $\text{Na}_2\text{S}$ : saturate  $\text{NaOH}$  solution with  $\text{H}_2\text{S}$ , then add as much  $\text{NaOH}$  as was used in the original solution.

**Sodium sulfite**,  $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$ —0.5N: 63 g per liter.

**Sodium sulfite, acid** (saturated): dissolve 600 g of  $\text{NaHSO}_3$  in water and dilute to 1 liter; for the preparation of addition compounds with aldehydes and ketones: prepare a saturated solution of sodium carbonate in water and saturate with sulfur dioxide.

**Sodium tartrate, acid**,  $\text{NaHC}_4\text{H}_4\text{O}_6$ : dissolve 1 part of the salt in 10 parts of water.

**Sodium thiosulfate**,  $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ : one part of the salt in 40 parts of water.

**Sonnenschein's reagent** (alkaloid detection): a nitric acid solution of ammonium molybdate is treated with phosphoric acid. The precipitate so produced is washed and boiled with aqua regia

until the ammonium salt is decomposed. The solution is evaporated to dryness and the residue is dissolved in 10%  $\text{HNO}_3$ .

**Stannic chloride**,  $\text{SnCl}_4$ —0.5N: 33 g per liter.

**Stannous chloride**,  $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$ —0.5N: 56 g per liter. The water should be acid with  $\text{HCl}$  and some metallic tin should be kept in the bottle.

**Starch solution** (iodine indicator): dissolve 5 g of soluble starch in cold water, pour the solution into 2 liters of water and boil for a few minutes. Keep in a glass-stoppered bottle.

**Starch solution** (other than soluble): make a thin paste of the starch with cold water, then stir in 200 times its weight of boiling water and boil for a few minutes. A few drops of chloroform added to the solution acts as a preservative.

**Stoke's reagent**: dissolve 30 g of ferrous sulfate and 20 g of tartaric acid in water and dilute to 1 liter. When required for use, add strong ammonia until the precipitate first formed is dissolved.

**Strontium chloride**,  $\text{SrCl}_2 \cdot 6\text{H}_2\text{O}$ —0.5N: 67 g per liter.

**Strontium nitrate**,  $\text{Sr}(\text{NO}_3)_2$ —0.5N: 53 g per liter.

**Strontium sulfate**,  $\text{SrSO}_4$ : prepare a saturated solution.

**Sulfanilic acid** (for detection of nitrites): dissolve 8 g of sulfanilic acid in 1 liter of acetic acid (sp. gr. 1.04).

**Sulfuric acid**,  $\text{H}_2\text{SO}_4$ —5N: 245 g per liter, sp. gr. 1.153.

**Sulfurous acid**,  $\text{H}_2\text{SO}_3$ : saturate water with sulfur dioxide.

**Tannic acid**: dissolve 1 g tannic acid in 1 mL alcohol and make up to 10 mL with water.

**Tartaric acid**,  $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$ : dissolve one part of the acid in 3 parts of water; for a saturated solution dissolve 750 g of tartaric acid in water and dilute to 1 liter.

**Tetrabromophenol blue**, tetrabromophenol-tetrabromosulfonphthalein (indicator): dissolve 0.1 g in 5 mL 0.02N  $\text{NaOH}$  and dilute with water to 250 mL; pH range yellow 3.0–4.6 blue.

**Thymol blue**, thymol-sulfonphthalein (indicator): dissolve 0.1 g in 10.75 mL 0.02N  $\text{NaOH}$  and dilute with water to 250 mL; or dissolve 0.1 g in 20 mL warm alcohol and dilute with water to 100 mL; pH range (acid) red 1.2–2.8 yellow, and (alkaline) yellow 8.0–9.6 blue.

**Thymolphthalein** (indicator): dissolve 0.1 g in 100 mL alcohol; pH range colorless 9.3–10.5 blue.

**Tincture of iodine** (antiseptic): add 70 g of iodine and 50 g of  $\text{KI}$  to 50 mL of water; make up to 1 liter with alcohol.

**o-Tolidine solution** (for residual chlorine in water analysis): dissolve 1 g of pulverized o-tolidine, m.p.  $129^\circ\text{C}$ ., in 1 liter of dilute hydrochloric acid (100 mL conc.  $\text{HCl}$  diluted to 1 liter).

**Toluylene red** (indicator): see neutral red.

**Trichloroacetic acid**: dissolve 100 g of the acid in water and dilute to 1 liter.

**Trinitrobenzene**, 1,3,5-trinitrobenzene (indicator): dissolve 0.1 g in 100 mL alcohol; pH range colorless 11.5–14.0 orange.

**Trinitrobenzoic acid**, 2,4,6-trinitrobenzoic acid (indicator): dissolve 0.1 g in 100 mL water; pH range colorless 12.0–13.4 orange-red.

**Tropeolin D** (indicator): see methyl orange.

**Tropeolin O**, sodium 2,4-dihydroxyazobenzene-4-sulfonate (indicator): dissolve 0.1 g in 100 mL water; pH range yellow 11.0–13.0 orange-brown.

**Tropeolin OO**, orange IV, sodium *p*-diphenylamino-azobenzene sulfonate, sodium 4'-anilino-azobenzene-4-sulfonate (indicator): dissolve 0.1 g in 100 mL water; pH range red 1.3–3.2 yellow.

**Tropeolin OOO**, sodium  $\alpha$ -naphtholazobenzene sulfonate (indicator): dissolve 0.1 g in 100 mL water; pH range yellow 7.6–8.9 red.

**Turmeric paper** (gives a rose-brown coloration with boric acid): wash the ground root of turmeric with water and discard the washings. Digest with alcohol and filter, using the clear filtrate to impregnate white, unsized paper, which is then dried.

**Uffelmann's reagent** (gives a yellow coloration in the presence of lactic acid): add a ferric chloride solution to a 2% phenol solution until the solution becomes violet in color.

**Wagner's solution** (phosphate rock analysis): dissolve 25 g citric acid and 1 g salicylic acid in water, and make up to 1 liter. Twenty-five to fifty milliliters of this reagent prevents precipitation of iron and aluminum.

**Wijs solution** (for iodine number): dissolve 13 g resublimed iodine in 1 liter of glacial acetic acid (99.5%), and pass in washed and dried (over or through  $\text{H}_2\text{SO}_4$ ) chlorine gas until the original thio titration of the solution is not quite doubled. There should be only a slight excess of iodine and no excess of chlorine. Preserve the solution in amber colored bottles sealed with paraffin. Do not use the solution after it has been prepared for more than 30 days.

**Xylene cyanole-methyl orange indicator**, Schoepfle modification (for partially color blind operators): dissolve 0.75 g xylene cyanole FF (Eastman No. T 1579) and 1.50 g methyl orange in 1 liter of water.

***p*-Xylenol blue**, 1,4-dimethyl-5-hydroxybenzene-sulfonphthalein (indicator): dissolve 0.1 g in 250 mL alcohol; pH range (acid) red 1.2–2.8 yellow, and (alkaline) yellow 8.0–9.6 blue.

**Zinc chloride**,  $\text{ZnCl}_2$ —0.5N: 34 g per liter.

**Zinc nitrate**,  $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ —0.5N: 74 g per liter.

**Zinc sulfate**,  $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ —0.5N: 72 g per liter.

**TABLE 11.49** TLV Concentration Limits for Gases and Vapors

Exposure limits (threshold limit value or TLV) are those set by the Occupational Safety and Health Administration and represent conditions to which most workers can be exposed without adverse effects. The TLV value is expressed as a time weighted average airborne concentration over a normal 8-hour workday and 40-hour work-week.

| Substance        | Maximum allowable exposure |                                 | Toxicity          |
|------------------|----------------------------|---------------------------------|-------------------|
|                  | ppm                        | $\text{mg} \cdot \text{m}^{-3}$ |                   |
| Acetaldehyde     | 25                         | 45                              | carcinogen        |
| Acetic acid      | 10                         | 25                              |                   |
| Acetic anhydride | 5                          | 21                              |                   |
| Acetone          | 750                        | 1780                            |                   |
| Acetonitrile     | 40                         | 67                              |                   |
| Acetophenone     | 10                         | 49                              | slightly narcotic |
| Acetylene        |                            |                                 |                   |
| Acrolein         | 0.1                        | 0.23                            |                   |

**TABLE 11.49** TLV Concentration Limits for Gases and Vapors (*Continued*)

| Substance                                          | Maximum allowable exposure |                      | Toxicity                           |
|----------------------------------------------------|----------------------------|----------------------|------------------------------------|

**TABLE 11.50** Some Common Reactive and Incompatible Chemicals

| Chemical             | Keep out of contact with                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Acetic acid          | Chromium(VI) oxide, chlorosulfonic acid, ethylene glycol, ethyleneimine, hydroxyl compounds, nitric acid, oleum, perchloric acid, peroxides, permanganates, potassium <i>tert</i> -butoxide, $\text{PCl}_3$                                                                                                                                                                    |
| Acetylene            | Bromine, chlorine, brass, copper and copper salts, fluorine, mercury and mercury salts, nitric acid, silver and silver salts, alkali hydrides, potassium metal                                                                                                                                                                                                                 |
| Alkali metals        | Moisture, acetylene, metal halides, ammonium salts, oxygen and oxidizing agents, halogens, carbon tetrachloride, carbon, carbon dioxide, carbon disulfide, chloroform, chlorinated hydrocarbons, ethylene oxide, boric acid, sulfur, tellurium                                                                                                                                 |
| Aluminum             | Chlorinated hydrocarbons, halogens, steam                                                                                                                                                                                                                                                                                                                                      |
| Ammonia, anhydrous   | Mercury, halogens, hypochlorites, chlorites, chlorine(I) oxide, hydrofluoric acid (anhydrous), hydrogen peroxide, chromium(VI) oxide, nitrogen dioxide, chromyl(VI) chloride, sulfinyl chloride, magnesium perchlorate, peroxodisulfates, phosphorus pentoxide, acetaldehyde, ethylene oxide, acrolein, gold(III) chloride                                                     |
| Ammonium nitrate     | Acids, metal powders, flammable liquids, chlorates, nitrites, sulfur, finely divided organic or combustible materials, perchlorates, urea                                                                                                                                                                                                                                      |
| Ammonium perchlorate | Hot copper tubing, sugar, finely divided organic or combustible materials, potassium periodate and permanganate, powdered metals, carbon, sulfur                                                                                                                                                                                                                               |
| Aniline              | Nitric acid, peroxides, oxidizing materials, acetic anhydride, chlorosulfonic acid, oleum, ozone                                                                                                                                                                                                                                                                               |
| Benzoyl peroxide     | Direct sunlight, sparks and open flames, shock and friction, acids, alcohols, amines, ethers, reducing agents, polymerization catalysts, metallic naphthenates                                                                                                                                                                                                                 |
| Bromine              | Ammonia, carbides, dimethylformamide, fluorine, ozone, olefins, reducing materials including many metals, phosphine, silver azide                                                                                                                                                                                                                                              |
| Calcium carbide      | Moisture, selenium, silver nitrate, sodium peroxide, tin(II) chloride, potassium hydroxide plus chlorine, HCl gas, magnesium                                                                                                                                                                                                                                                   |
| Carbon, activated    | Calcium hypochlorite, all oxidizing agents, unsaturated oils                                                                                                                                                                                                                                                                                                                   |
| Chlorates            | Ammonium salts, acids, metal powders, sulfur, finely divided organic or combustible materials, cyanides, metal sulfides, manganese dioxide, sulfur dioxide, organic acids                                                                                                                                                                                                      |
| Chlorine             | Ammonia, acetylene, alcohols, alkanes, benzene, butadiene, carbon disulfide, dibutyl phthalate, ethers, fluorine, glycerol, hydrocarbons, hydrogen, sodium carbide, finely divided metals, metal acetylides and carbides, nitrogen compounds, nonmetals, nonmetal hydrides, phosphorus compounds, polychlorobiphenyl, silicones, steel, sulfides, synthetic rubber, turpentine |
| Chlorine dioxide     | Ammonia, carbon monoxide, hydrogen, hydrogen sulfide, methane, mercury, nonmetals, phosphine, phosphorus pentachloride                                                                                                                                                                                                                                                         |
| Chlorites            | Ammonia, organic matter, metals                                                                                                                                                                                                                                                                                                                                                |
| Chloroform           | Aluminum, magnesium, potassium, sodium, aluminum chloride, ethylene, powerful oxidants                                                                                                                                                                                                                                                                                         |
| Chlorosulfonic acid  | Saturated and unsaturated acids, acid anhydrides, nitriles, acrolein, alcohols, ammonia, esters, HCl, HF, ketones, hydrogen peroxide, metal powders, nitric acid, organic materials, water                                                                                                                                                                                     |
| Chromic(VI) acid     | Acetic acid, acetic anhydride, acetone, alcohols, alkali metals, ammonia, dimethylformamide, camphor, glycerol, hydrogen sulfide, phosphorus, pyridine, selenium, sulfur, turpentine, flammable liquids in general                                                                                                                                                             |
| Cobalt               | Acetylene, hydrazinium nitrate, oxidants                                                                                                                                                                                                                                                                                                                                       |
| Copper               | Acetylene and alkynes, ammonium nitrate, azides, bromates, chlorates, iodates, chlorine, ethylene oxide, fluorine, peroxides, hydrogen sulfide, hydrazinium nitrate                                                                                                                                                                                                            |

**TABLE 11.50** Some Common Reactive and Incompatible Chemicals (*Continued*)

| Chemical              | Keep out of contact with                                                                                                                                                                                           |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Copper(II) sulfate    | Hydroxylamine, magnesium                                                                                                                                                                                           |
| Cumene hydroperoxide  | Acids (inorganic or organic)                                                                                                                                                                                       |
| Cyanides              | Acids, water or steam, fluorine, magnesium, nitric acid and nitrates, nitrites                                                                                                                                     |
| Cyclohexanol          | Oxidants                                                                                                                                                                                                           |
| Cyclohexanone         | Hydrogen peroxide, nitric acid                                                                                                                                                                                     |
| Decaborane-14         | Dimethyl sulfoxide, ethers, halocarbons                                                                                                                                                                            |
| Diazomethane          | Alkali metals, calcium sulfate                                                                                                                                                                                     |
| 1,1-Dichloroethylene  | Air, chlorotrifluoroethylene, ozone, perchloryl fluoride                                                                                                                                                           |
| Dimethylformamide     | Halocarbons, inorganic and organic nitrates, bromine, chromium(VI) oxide, aluminum trimethyl, phosphorus trioxide                                                                                                  |
| 1,1-Dimethylhydrazine | Air, hydrogen peroxide, nitric acid, nitrous oxide                                                                                                                                                                 |
| Dimethylsulfoxide     | Acyl and aryl halides, boron compounds, bromomethane, nitrogen dioxide, magnesium perchlorate, periodic acid, silver difluoride, sodium hydride, sulfur trioxide                                                   |
| Dinitrobenzenes       | Nitric acid                                                                                                                                                                                                        |
| Dinitrotoluenes       | Nitric acid                                                                                                                                                                                                        |
| 1,4-Dioxane           | Silver perchlorate                                                                                                                                                                                                 |
| Esters                | Nitrates                                                                                                                                                                                                           |
| Ethylamine            | Cellulose, oxidizers                                                                                                                                                                                               |
| Ethers                | Oxidizing materials, boron triiodide                                                                                                                                                                               |
| Ethylene              | Aluminum trichloride, carbon tetrachloride, chlorine, nitrogen oxides, tetrafluoroethylene                                                                                                                         |
| Ethylene oxide        | Acids and bases, alcohols, air, 1,3-nitroaniline, aluminum chloride, aluminum oxide, ammonia, copper, iron chlorides and oxides, magnesium perchlorate, mercaptans, potassium, tin chlorides, alkane thiols        |
| Ethyl ether           | Liquid air, chlorine, chromium(VI) oxide, lithium aluminum hydride, ozone, perchloric acid, peroxides                                                                                                              |
| Ethyl sulfate         | Oxidizing materials, water                                                                                                                                                                                         |
| Flammable liquids     | Ammonium nitrate, chromic acid, the halogens, hydrogen peroxide, nitric acid                                                                                                                                       |
| Fluorine              | Isolate from everything; only lead and nickel resist prolonged attack                                                                                                                                              |
| Formamide             | Iodine, pyridine, sulfur trioxide                                                                                                                                                                                  |
| Freon 113             | Aluminum, barium, lithium, samarium, NaK alloy, titanium                                                                                                                                                           |
| Glycerol              | Acetic anhydride, hypochlorites, chromium(VI) oxide, perchlorates, alkali peroxides, sodium hydride                                                                                                                |
| Hydrazine             | Alkali metals, ammonia, chlorine, chromates and dichromates, copper salts, fluorine, hydrogen peroxide, metallic oxides, nickel, nitric acid, liquid oxygen, zinc diethyl                                          |
| Hydrides              | Powerful oxidizing agents, moisture                                                                                                                                                                                |
| Hydrocarbons          | Halogens, chromium(VI) oxide, peroxides                                                                                                                                                                            |
| Hydrogen              | Halogens, lithium, oxidants, lead trifluoride                                                                                                                                                                      |
| Hydrogen bromide      | Fluorine, iron(III) oxide, ammonia, ozone                                                                                                                                                                          |
| Hydrogen chloride     | Acetic anhydride, aluminum, 2-aminoethanol, ammonia, chlorosulfonic acid, ethylenediamine, fluorine, metal acetylides and carbides, oleum, perchloric acid, potassium permanganate, sodium, sulfuric acid          |
| Hydrogen fluoride     | Acetic anhydride, 2-aminoethanol, ammonia, arsenic trioxide, chlorosulfonic acid, ethylenediamine, ethyleneimine, fluorine, HgO, oleum, phosphorus trioxide, propylene oxide, sodium, sulfuric acid, vinyl acetate |
| Hydrogen iodide       | Fluorine, nitric acid, ozone, metals                                                                                                                                                                               |
| Hydrogen peroxide     | Copper, chromium, iron, most metals or their salts, alcohols, acetone, organic materials, flammable liquids, combustible materials                                                                                 |
| Hydrogen selenide     | Hydrogen peroxide, nitric acid                                                                                                                                                                                     |
| Hydrogen sulfide      | Fuming nitric acid, oxidizing gases, peroxides                                                                                                                                                                     |

**TABLE 11.50** Some Common Reactive and Incompatible Chemicals (*Continued*)

| Chemical                  | Keep out of contact with                                                                                                                                                                                                                          |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hydroquinone              | Sodium hydroxide                                                                                                                                                                                                                                  |
| Hydroxylamine             | Barium oxide and peroxide, carbonyls, chlorine, copper(II) sulfate, dichromates, lead dioxide, phosphorus trichloride and pentachloride, permanganates, pyridine, sodium, zinc                                                                    |
| Hypochlorites, salts of   | Urea, amines, anthracene, carbon, carbon tetrachloride, ethanol, glycerol, mercaptans, organic sulfides, sulfur, thiols                                                                                                                           |
| Indium                    | Acetonitrile, nitrogen dioxide, mercury(II) bromide, sulfur                                                                                                                                                                                       |
| Iodine                    | Acetaldehyde, acetylene, aluminum, ammonia (aqueous or anhydrous), antimony, bromine pentafluoride, carbides, cesium oxide, chlorine, ethanol, fluorine, formamide, lithium, magnesium, phosphorus, pyridine, silver azide, sulfur trioxide       |
| Iodine monochloride       | Aluminum foil, organic matter, metal sulfides, phosphorus, potassium, rubber, sodium                                                                                                                                                              |
| Iodoform                  | Acetone, lithium, mercury(II) oxide, mercury(I) chloride, silver nitrate                                                                                                                                                                          |
| Iodomethane               | Silver chloride, sodium                                                                                                                                                                                                                           |
| Iron disulfide            | Water, powdered pyrites                                                                                                                                                                                                                           |
| Isothiourea               | Acrylaldehyde, hydrogen peroxide, nitric acid                                                                                                                                                                                                     |
| Ketones                   | Aldehydes, nitric acid, perchloric acid                                                                                                                                                                                                           |
| Lactonitrile              | Oxidizing materials                                                                                                                                                                                                                               |
| Lead                      | Ammonium nitrate, chlorine trifluoride, hydrogen peroxide, sodium azide and carbide, zirconium, oxidants                                                                                                                                          |
| Lead(II) azide            | Calcium stearate, copper, zinc, brass, carbon disulfide                                                                                                                                                                                           |
| Lead chromate             | Iron hexacyanoferrate(4-)                                                                                                                                                                                                                         |
| Lead dioxide              | Aluminum carbide, hydrogen peroxide, hydrogen sulfide, hydroxylamine, nitroalkanes, nitrogen compounds, nonmetal halides, peroxyformic acid, phosphorus, phosphorus trichloride, potassium, sulfur, sulfur dioxide, sulfides, tungsten, zirconium |
| Lead(II) oxide            | Chlorinated rubber, chlorine, ethylene, fluorine, glycerol, metal acetylides, perchloric acid                                                                                                                                                     |
| Lead(II,IV) oxide         | Same as for lead dioxide                                                                                                                                                                                                                          |
| Lithium hydride           | Nitrous oxide, oxygen                                                                                                                                                                                                                             |
| Magnesium                 | Air, beryllium fluoride, ethylene oxide, halogens, halocarbons, HI, metal cyanides, metal oxides, metal oxosalts, methanol, oxidants, peroxides, sulfur, tellurium                                                                                |
| Maleic anhydride          | Alkali metals, amines, KOH, NaOH, pyridine                                                                                                                                                                                                        |
| Manganese dioxide         | Aluminum, hydrogen sulfide, oxidants, potassium azide, hydrogen peroxide, peroxosulfuric acid, sodium peroxide                                                                                                                                    |
| Mercaptans                | Powerful oxidizers                                                                                                                                                                                                                                |
| Mercury                   | Acetylenic compounds, chlorine, fulminic acid, ammonia, ethylene oxide, metals, methyl azide, oxidants, tetracarbonylnickel                                                                                                                       |
| Mercury(II) cyanide       | Fluorine, hydrogen cyanide, magnesium, sodium nitrite                                                                                                                                                                                             |
| Mercury(I) nitrate        | Phosphorus                                                                                                                                                                                                                                        |
| Mercury(II) nitrate       | Acetylene, aromatics, ethanol, hypophosphoric acid, phosphine, unsaturated organic compounds                                                                                                                                                      |
| Mercury(II) oxide         | Chlorine, hydrazine hydrate, hydrogen peroxide, hypophosphorous acid, magnesium, phosphorus, sulfur, butadiene, hydrocarbons, methanethiol                                                                                                        |
| Mesityl oxide             | 2-Aminoethanol, chlorosulfonic acid, nitric acid, ethylenediamine, sulfuric acid                                                                                                                                                                  |
| Methanol                  | Beryllium dihydride, chloroform, oxidants, potassium <i>tert</i> -butoxide                                                                                                                                                                        |
| Methylamine               | Nitromethane                                                                                                                                                                                                                                      |
| <i>N</i> -Methylformamide | Benzenesulfonyl chloride                                                                                                                                                                                                                          |
| Methyl isobutyl ketone    | Potassium <i>tert</i> -butoxide                                                                                                                                                                                                                   |

**TABLE 11.50** Some Common Reactive and Incompatible Chemicals (*Continued*)

| Chemical                 | Keep out of contact with                                                                                                                                                                                                                    |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Methyl methacrylate      | Air, benzoyl peroxide                                                                                                                                                                                                                       |
| 4-Methylnitrobenzene     | Sulfuric acid, tetranitromethane                                                                                                                                                                                                            |
| 2-Methylpyridine         | Hydrogen peroxide, iron(II) sulfate, sulfuric acid                                                                                                                                                                                          |
| Methylsodium             | 4-Chloronitrobenzene                                                                                                                                                                                                                        |
| Molybdenum trioxide      | Chlorine trifluoride, interhalogens, metals                                                                                                                                                                                                 |
| Naphthalene              | Chromium trioxide, dinitrogen pentaoxide                                                                                                                                                                                                    |
| 2-Naphthol               | Antipyrine, camphor, phenol, iron(III) salts, menthol, oxidizing materials, permanganates, urethane                                                                                                                                         |
| Neodymium                | Phosphorus                                                                                                                                                                                                                                  |
| Nickel                   | Aluminum, aluminum(III) chloride, ethylene, 1,4-dioxan, hydrogen, methanol, nonmetals, oxidants, sulfur compounds                                                                                                                           |
| Nickel carbonyl          | Air, bromine, oxidizing materials                                                                                                                                                                                                           |
| Niobium                  | Bromine trifluoride, chlorine, fluorine                                                                                                                                                                                                     |
| Nitrates                 | Aluminum, BP, cyanides, esters, phosphorus, tin(II) chloride, sodium hypophosphite, thiocyanates                                                                                                                                            |
| Nitric acid, fuming      | Organic matter, nonmetals, most metals, ammonia, chlorosulfonic acid, chromium trioxide, cyanides, dichromates, hydrazines, hydrides, HCN, HI, hydrogen sulfide, sulfur dioxide, sulfur halides, sulfuric acid, flammable liquids and gases |
| Nitric oxide             | Aluminum, BaO, boron, carbon disulfide, chromium, many chlorinated hydrocarbons, fluorine, hydrocarbons, ozone, phosphine, phosphorus, hydrazine, acetic anhydride, ammonia, chloroform, Fe, K, Mg, Mn, Na, sulfur                          |
| Nitrites                 | Organic nitrites in contact with ammonium salts, cyanides                                                                                                                                                                                   |
| Nitrobenzene             | Nitric acid, nitrous oxide, silver perchlorate                                                                                                                                                                                              |
| Nitroethane              | Hydroxides, hydrocarbons, metal oxides                                                                                                                                                                                                      |
| Nitrogen trichloride     | Ammonia, As, hydrogen sulfide, nitrogen dioxide, organic matter, ozone, phosphine, phosphorus, KCN, KOH, Se, dibutyl ether                                                                                                                  |
| Nitrogen dioxide         | Cyclohexane, fluorine, formaldehyde, alcohols, nitrobenzene, petroleum, toluene                                                                                                                                                             |
| Nitrogen triiodide       | Acids, bromine, chlorine, hydrogen sulfide, ozone                                                                                                                                                                                           |
| $\alpha$ -Nitroguanidine | Complex salts of mercury and silver                                                                                                                                                                                                         |
| Nitromethane             | Acids, alkylmetal halides, hydroxides, hydrocarbons, organic amines, formaldehyde, nitric acid, perchlorates                                                                                                                                |
| 1-Nitropropane           | See under Nitromethane; chlorosulfonic acid, oleum                                                                                                                                                                                          |
| Nitrosyl fluoride        | Haloalkenes, metals, nonmetals                                                                                                                                                                                                              |
| Nitrosyl perchlorate     | Acetones, amines, diethyl ether, metal salts, organic materials                                                                                                                                                                             |
| Nitrourea                | Mercury(II) and silver salts                                                                                                                                                                                                                |
| Nitrous acid             | Phosphine, phosphorus trichloride, silver nitrate, semicarbazone                                                                                                                                                                            |
| Nitryl chloride          | Ammonia, sulfur trioxide, tin(IV) bromide and iodide                                                                                                                                                                                        |
| Oxalic acid              | Furfuryl alcohol, silver, mercury, sodium chlorate, sodium chlorite, sodium hypochlorite                                                                                                                                                    |
| Oxygen                   | Acetaldehyde, acetone, alcohols, alkali metals, alkaline earth metals, Al-Ti alloys, ether, carbon disulfide, halocarbons, hydrocarbons, metal hydrides, 1,3,5-trioxane                                                                     |
| Ozone                    | Alkenes, aromatic compounds, bromine, diethyl ether, ethylene, HBr, HI, nitric oxide, nitrogen dioxide, rubber, stibine                                                                                                                     |
| Palladium                | Arsenic, carbon, ozonides, sulfur, sodium tetrahydridoborate                                                                                                                                                                                |
| Paraformaldehyde         | Liquid oxygen                                                                                                                                                                                                                               |
| Paraldehyde              | Alkalies, HCN, iodides, nitric acid, oxidizers                                                                                                                                                                                              |
| Pentaborane-9            | Dimethylsulfoxide                                                                                                                                                                                                                           |
| Pentacarbonyliron        | Acetic acid, nitric oxide, transition metal halides, water, zinc                                                                                                                                                                            |

**TABLE 11.50** Some Common Reactive and Incompatible Chemicals (*Continued*)

| Chemical                        | Keep out of contact with                                                                                                                                                                                                                                                                                                     |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2-Pentanone                     | Bromine trifluoride                                                                                                                                                                                                                                                                                                          |
| 3-Pentanone                     | Hydrogen peroxide, nitric acid                                                                                                                                                                                                                                                                                               |
| Perchlorates                    | Carbonaceous materials, finely divided metals particularly magnesium and aluminum, sulfur, benzene, olefins, ethanol, sulfur, sulfuric acid                                                                                                                                                                                  |
| Perchloric acid                 | Acetic acid, acetic anhydride, alcohols, antimony compounds, azo pigments, bismuth and its alloys, methanol, carbonaceous materials, carbon tetrachloride, cellulose, dehydrating agents, diethyl ether, glycols and glycolethers, HCl, HI, hypophosphites, ketones, nitric acid, pyridine, steel, sulfoxides, sulfuric acid |
| Permanganates                   | All reducing agents, organic materials                                                                                                                                                                                                                                                                                       |
| Peroxides                       | Reducing agents, organic materials, thiocyanates                                                                                                                                                                                                                                                                             |
| Peroxoacetic acid               | Acetic anhydride, olefins, organic matter                                                                                                                                                                                                                                                                                    |
| Peroxybenzoic acid              | Olefins, reducing materials                                                                                                                                                                                                                                                                                                  |
| Peroxoformic acid               | Metals and nonmetals, organic materials                                                                                                                                                                                                                                                                                      |
| Peroxyosulfuric acid            | Acetone, alcohols, aromatic compounds, catalysts                                                                                                                                                                                                                                                                             |
| Phenol                          | Butadiene, peroxodisulfuric acid, peroxosulfuric acid, aluminum chloride plus nitrobenzene                                                                                                                                                                                                                                   |
| Phenylhydrazine                 | Lead dioxide, oxidizers                                                                                                                                                                                                                                                                                                      |
| Phosgene                        | Aluminum, alkali metals, 2-propanol                                                                                                                                                                                                                                                                                          |
| Phosphine                       | Air, boron trichloride, bromine, chlorine, nitric acid, nitrogen oxides, nitrous acid, oxygen, silver nitrate                                                                                                                                                                                                                |
| Phosphorus pentachloride        | Aluminum, chlorine, chlorine dioxide, chlorine trioxide, fluorine, magnesium oxide, nitrobenzene, diphosphorus trioxide, potassium, sodium, urea, water                                                                                                                                                                      |
| Phosphorus pentafluoride        | Water or steam                                                                                                                                                                                                                                                                                                               |
| Phosphorus pentasulfide         | Air, alcohols, water                                                                                                                                                                                                                                                                                                         |
| Phosphorus pentoxide            | Formic acid, HF, inorganic bases, metals, oxidants, water                                                                                                                                                                                                                                                                    |
| Phosphorus, red                 | Organic materials                                                                                                                                                                                                                                                                                                            |
| Phosphorus tribromide           | Potassium, ruthenium tetroxide, sodium, water                                                                                                                                                                                                                                                                                |
| Phosphorus trichloride          | Acetic acid, aluminum, chromyl dichloride, dimethylsulfoxide, hydroxylamine, lead dioxide, nitric acid, nitrous acid, organic matter, potassium, sodium water                                                                                                                                                                |
| Phosphorus, white               | Air, oxidants of all types, halogens, metals                                                                                                                                                                                                                                                                                 |
| Phosphoryl chloride             | Carbon disulfide, <i>N,N</i> -dimethylformamide, 2,5-dimethylpyrrole, 2,6-dimethylpyridine 1-oxide, dimethylsulfoxide, water, zinc                                                                                                                                                                                           |
| Phthalic acid                   | Nitric acid, sodium nitrite                                                                                                                                                                                                                                                                                                  |
| Piperazine                      | Oxidizers                                                                                                                                                                                                                                                                                                                    |
| Platinum                        | Acetone, arsenic, hydrazine, lithium, peroxosulfuric acid, phosphorus, selenium, tellurium                                                                                                                                                                                                                                   |
| Potassium                       | <i>See under</i> Alkali metals                                                                                                                                                                                                                                                                                               |
| Potassium <i>tert</i> -butoxide | Organic compounds, sulfuric acid                                                                                                                                                                                                                                                                                             |
| Potassium hydride               | Air, chlorine, acetic acid, acrolein, acrylonitrile, maleic anhydride, nitroparaffins, <i>N</i> -nitrosomethylurea, tetrahydrofuran, water                                                                                                                                                                                   |
| Potassium perchlorate           | Aluminum plus magnesium, carbon, nickel plus titanium, reducing agents, sulfur, sulfuric acid                                                                                                                                                                                                                                |
| Potassium permanganate          | Organic or readily oxidizable materials                                                                                                                                                                                                                                                                                      |
| Potassium sodium alloy          | Air, carbon dioxide, carbon disulfide, halocarbons, metal oxides                                                                                                                                                                                                                                                             |
| 2-Propyn-1-ol                   | Alkali metals, mercury(II) sulfate, oxidizing materials, phosphorus pentoxide, sulfuric acid                                                                                                                                                                                                                                 |
| Pyridine                        | Chlorosulfonic acid, chromium trioxide, formamide, maleic anhydride, nitric acid, oleum, perchromates, silver perchlorate, sulfuric acid                                                                                                                                                                                     |
| Pyrrolidine                     | Oxidizing materials                                                                                                                                                                                                                                                                                                          |

**TABLE 11.50** Some Common Reactive and Incompatible Chemicals (*Continued*)

| Chemical              | Keep out of contact with                                                                                                                                                                                                |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Quinoline             | Dinitrogen tetroxide, linseed oil, maleic anhydride, thionyl chloride                                                                                                                                                   |
| Salicylic acid        | Iodine, iron salts, lead acetate                                                                                                                                                                                        |
| Silicon               | Alkali carbonates, calcium, chlorine, cobalt(II) fluoride, manganese trifluoride, oxidants, silver fluoride, sodium-potassium alloy                                                                                     |
| Silver                | Acetylene, ammonium compounds, ethyleneimine, hydrogen peroxide, oxalic acid, sulfuric acid, tartaric acid                                                                                                              |
| Sodium                | See under Alkali metals                                                                                                                                                                                                 |
| Sodium peroxide       | Glacial acetic acid, acetic anhydride, aniline, benzene, benzaldehyde, carbon disulfide, diethyl ether, ethanol or methanol, ethylene glycol, ethyl acetate, furfural, glycerol, metals, methyl acetate, organic matter |
| Sulfides              | Acids, powerful oxidizers, moisture                                                                                                                                                                                     |
| Sulfur                | Oxidizing materials, halogens                                                                                                                                                                                           |
| Sulfur dioxide        | Halogens, metal oxides, polymeric tubing, potassium chlorate, sodium hydride                                                                                                                                            |
| Sulfuric acid         | Chlorates, metals, HCl, organic materials, perchlorates, permanganates, water                                                                                                                                           |
| Sulfuryl dichloride   | Alkalis, diethyl ether, dimethylsulfoxide, dinitrogen tetroxide, lead dioxide, phosphorus                                                                                                                               |
| Tellurium             | Halogens, metals                                                                                                                                                                                                        |
| Tetrahydrofuran       | Tetrahydroaluminates, KOH, NaOH                                                                                                                                                                                         |
| Tetranitroaniline     | Reducing materials                                                                                                                                                                                                      |
| Tetranitromethane     | Aluminum, cotton, aromatic nitro compounds, hydrocarbons, cotton, toluene                                                                                                                                               |
| Thiocyanates          | Chlorates, nitric acid, peroxides                                                                                                                                                                                       |
| Thionyl chloride      | Ammonia, dimethylsulfoxide, linseed oil, quinoline, sodium                                                                                                                                                              |
| Thiophene             | Nitric acid                                                                                                                                                                                                             |
| Thymol                | Acetanilide, antipyrine, camphor, chlorohydrate, menthol, quinine sulfate, urethane                                                                                                                                     |
| Tin(II) chloride      | Boron trifluoride, ethylene oxide, hydrazine hydrate, nitrates, Na, K, hydrogen peroxide                                                                                                                                |
| Tin(IV) chloride      | Alkyl nitrates, ethylene oxide, K, Na turpentine                                                                                                                                                                        |
| Titanium              | Aluminum, boron trifluoride, carbon dioxide, CuO, halocarbons, halogens, PbO, nitric acid, potassium chlorate, potassium nitrate, potassium permanganate, steam at high temperatures, water                             |
| Toluene               | Sulfuric plus nitric acids, nitrogen dioxide, silver perchlorate, uranium hexafluoride                                                                                                                                  |
| Toluidines            | Nitric acid                                                                                                                                                                                                             |
| 2,4,6-Trinitrotoluene | Sodium dichromate, sulfuric acid                                                                                                                                                                                        |
| 1,3,5-Trioxane        | Oxidizing materials, acids                                                                                                                                                                                              |
| Urea                  | Sodium nitrite, phosphorus pentachloride                                                                                                                                                                                |
| Vinylidene chloride   | Chlorosulfonic acid, nitric acid, oleum                                                                                                                                                                                 |

TABLE 11.51 Chemicals Recommended for Refrigerated Storage

| A. Due to chemical decomposition or polymerization |                                        |
|----------------------------------------------------|----------------------------------------|
| Acetaldehyde                                       | Isoprene                               |
| Acrolein                                           | Lecithin                               |
| Adenosinetriphosphoric acid                        | Mercaptoacetic acid                    |
| Bromacetaldehyde, diethyl acetal                   | Methyl acrylate                        |
| Bromosuccinimide                                   | 2-Methyl-1-butene                      |
| 3-Buten-2-one                                      | Methylenedi-1,4-phenylene diisocyanate |
| tert-Butyl hydroperoxide                           | 4-Methyl-1-pentene                     |
| 2-Chlorocyclohexanone                              | α-Methylstyrene                        |
| Cupferron                                          | 1-Naphthyl isocyanate                  |
| 1,3-Cyclohexadiene                                 | 1-Pentene                              |
| 1,3-Dihydroxy-2-propanone                          | Isopentyl acetate                      |
| Divinylbenzene                                     | Pyruvic acid                           |
| Ethyl methacrylate, monomer                        | Styrene, stabilized                    |
| Glutathione                                        | Tetramethylsilane                      |
| Glycidol                                           | Thioacetamide                          |
| Histamine, base                                    | Veratraldehyde                         |
| Hydrocinnamaldehyde                                | Vitamin E (and the acetate)            |
| B. Due to flammability and high volatility         |                                        |
| Acetaldehyde                                       | Iodomethane                            |
| Bromoethane                                        | Isoprene                               |
| tert-Butylamine                                    | Isopropylamine                         |
| Carbon disulfide                                   | Methylal                               |
| 1-Chloropropane                                    | 2-Methylbutane                         |
| 3-Chloropropane                                    | 2-Methyl-2-butene                      |
| Cyclopentane                                       | Methyl formate                         |
| Diethyl ether                                      | Pentane                                |
| 2,2-Dimethylbutane                                 | Propylamine                            |
| Dimethyl sulfide                                   | Propylene oxide                        |
| Furan                                              | Trichlorosilane                        |

TABLE 11.52 Chemicals Which Polymerize or Decompose on Extended Refrigeration

|                                        |                   |
|----------------------------------------|-------------------|
| Formaldehyde                           | Sodium methoxide  |
| Hydrogen peroxide                      | Sodium nitrate    |
| Sodium chlorite [sodium chlorate (IV)] | Sodium peroxide   |
| Sodium chromate(VI)                    | Strontium nitrate |
| Sodium dithionite                      | Urea              |
| Sodium ethoxide                        |                   |

11.8 SIEVES AND SCREENS

TABLE 11.53 U.S. Standard Sieve Series

| Sieve no. | Sieve opening |        | Sieve no. | Sieve opening |        |

Specifications are from ASTM E.11-81/ISO 565. The sieve numbers are the approximate number of openings per linear inch.

11.9 THERMOMETRY

11.9.1 Temperature and Its Measurement

The new international temperature scale, known as ITS-90, was adopted in September 1989. However, neither the definition of thermodynamic temperature nor the definition of the kelvin or the Celsius temperature scales has changed; it is the way in which we are to realize these definitions that has changed. The changes concern the recommended thermometers to be used in different regions of the temperature scale and the list of secondary standard fixed points. The changes in temperature determined using ITS-90 from the previous IPTS-68 are always less than 0.4 K, and almost always less than 0.2 K, over the range 0–1300 K.

The ultimate definition of thermodynamic temperature is in terms of  $pV$  (pressure  $\times$  volume) in a gas thermometer extrapolated to low pressure. The kelvin (K), the unit of thermodynamic temperature, is defined by specifying the temperature of one fixed point on the scale—the triple point

of water which is defined to be 273.16 K. The Celsius temperature scale ( $^{\circ}\text{C}$ ) is defined by the equation

$$^{\circ}\text{C} = \text{K} - 273.15$$

where the freezing point of water at 1 atm is 273.15 K.

The fixed points in the ITS-90 are given in Table 11.39. Platinum resistance thermometers are recommended for use between 14 K and 1235 K (the freezing point of silver), calibrated against the fixed points. Below 14 K either the vapor pressure of helium or a constant-volume gas thermometer is to be used. Above 1235 K radiometry is to be used in conjunction with the Planck radiation law,

$$L_{\lambda} = c_1 \lambda^{-5} (e^{c_2/\lambda T} - 1)^{-1}$$

where  $L_{\lambda}$  is the spectral radiance at wavelength  $\lambda$ . The first radiation constant,  $c_1$ , is  $3.741\,83 \times 10^{-16} \text{ W} \cdot \text{m}^2$  and the second radiation constant,  $c_2$ , has a value of  $0.014\,388 \text{ m} \cdot \text{K}$ .

**TABLE 11.54** Fixed Points in the ITS-90

| Fixed points                                              | $T$ , K  | $t$ , $^{\circ}\text{C}$ |
|-----------------------------------------------------------|----------|--------------------------|
| Triple point of hydrogen                                  | 13.8033  | − 259.3467               |
| Boiling point of hydrogen at 33 321.3 Pa                  | 17.035   | − 256.115                |
| Boiling point of hydrogen at 101 292 Pa                   | 20.27    | − 252.88                 |
| Triple point of neon                                      | 24.5561  | − 248.5939               |
| Triple point of oxygen                                    | 54.3584  | − 218.7916               |
| Triple point of argon                                     | 83.8058  | − 189.3442               |
| Triple point of mercury                                   | 234.3156 | − 38.8344                |
| Triple point of water                                     | 273.16   | 0.01                     |
| Melting point of gallium                                  | 302.9146 | 29.7646                  |
| Freezing point of indium                                  | 429.7458 | 156.5985                 |
| Freezing point of tin                                     | 505.078  | 231.928                  |
| Freezing point of zinc                                    | 692.677  | 419.527                  |
| Freezing point of aluminum                                | 933.473  | 660.323                  |
| Freezing point of silver                                  | 1234.93  | 961.78                   |
| Freezing point of gold                                    | 1337.33  | 1064.18                  |
| Freezing point of copper                                  | 1357.77  | 1084.62                  |

11.10 THERMOCOUPLES

The thermocouple reference data in Tables 11.55 to 11.63 give the thermoelectric voltage in millivolts with the reference junction at  $0^{\circ}\text{C}$ . Note that the temperature for a given entry is obtained by adding the corresponding temperature in the top row to that in the left-hand column, regardless of whether the latter is positive or negative.

The noble metal thermocouples, Types B, R, and S, are all platinum or platinum-rhodium thermocouples and hence share many of the same characteristics. Metallic vapor diffusion at high temperatures can readily change the platinum wire calibration, hence platinum wires should only be used inside a nonmetallic sheath such as high-purity alumina.

Type B thermocouples (Table 11.56) offer distinct advantages of improved stability, increased mechanical strength, and higher possible operating temperatures. They have the unique advantage that the reference junction potential is almost immaterial, as long as it is between 0°C and 40°C. Type B is virtually useless below 50°C because it exhibits a double-value ambiguity from 0°C to 42°C.

Type E thermoelements (Table 11.57) are very useful down to about liquid hydrogen temperatures and may even be used down to liquid helium temperatures. They are the most useful of the commercially standardized thermocouple combinations for subzero temperature measurements because of their high Seebeck coefficient (58  $\mu\text{V}/^\circ\text{C}$ ), low thermal conductivity, and corrosion resistance. They also have the largest Seebeck coefficient (voltage response per degree Celsius) above 0°C of any of the standardized thermocouples which makes them useful for detecting small temperature changes. They are recommended for use in the temperature range from  $-250$  to  $871^\circ\text{C}$  in oxidizing or inert atmospheres. They should not be used in sulfurous, reducing, or alternately reducing and oxidizing atmospheres unless suitably protected with tubes. They should not be used in vacuum at high temperatures for extended periods of time.

Type J thermocouples (Table 11.58) are one of the most common types of industrial thermocouples because of the relatively high Seebeck coefficient and low cost. They are recommended for use in the temperature range from 0 to  $760^\circ\text{C}$  (but never above  $760^\circ\text{C}$  due to an abrupt magnetic transformation that can cause decalibration even when returned to lower temperatures). Use is permitted in vacuum and in oxidizing, reducing, or inert atmospheres, with the exception of sulfurous atmospheres above  $500^\circ\text{C}$ . For extended use above  $500^\circ\text{C}$ , heavy-gauge wires are recommended. They are not recommended for subzero temperatures. These thermocouples are subject to poor conformance characteristics because of impurities in the iron.

The Type K thermocouple (Table 11.59) is more resistant to oxidation at elevated temperatures than the Type E, J, or T thermocouple, and consequently finds wide application at temperatures above  $500^\circ\text{C}$ . It is recommended for continuous use at temperatures within the range  $-250$  to  $1260^\circ\text{C}$  in inert or oxidizing atmospheres. It should not be used in sulfurous or reducing atmospheres, or in vacuum at high temperatures for extended times.

The Type N thermocouple (Table 11.60) is similar to Type K but it has been designed to minimize some of the instabilities in the conventional Chromel-Alumel combination. Changes in the alloy content have improved the order/disorder transformations occurring at  $500^\circ\text{C}$  and a higher silicon content of the positive element improves the oxidation resistance at elevated temperatures.

The Type R thermocouple (Table 11.61) was developed primarily to match a previous platinum–10% rhodium British wire which was later found to have 0.34% iron impurity in the rhodium. Comments on Type S also apply to Type R.

The Type S thermocouple (Table 11.62) is so stable that it remains the standard for determining temperatures between the antimony point ( $630.74^\circ\text{C}$ ) and the gold point ( $1064.43^\circ\text{C}$ ). The other fixed point used is that of silver. The Type S thermocouple can be used from  $-50^\circ\text{C}$  continuously up to about  $1400^\circ\text{C}$ , and intermittently at temperatures up to the freezing point of platinum ( $1769^\circ\text{C}$ ). The thermocouple is most reliable when used in a clean oxidizing atmosphere, but may also be used in inert gaseous atmospheres or in a vacuum for short periods of time. It should not be used in reducing atmospheres, nor in those containing metallic vapor (such as lead or zinc), nonmetallic vapors (such as arsenic, phosphorus, or sulfur), or easily reduced oxides, unless suitably protected with nonmetallic protecting tubes.

The Type T thermocouple (Table 11.63) is popular for the temperature region below  $0^\circ\text{C}$  (but see under Type E). It can be used in vacuum, or in oxidizing, reducing, or inert atmospheres.

11.11 CORRECTION FOR EMERGENT STEM OF THERMOMETERS

When a thermometer which has been standardized for total immersion is used with a part of the liquid column at a temperature below that of the bulb, the reading is low and a correction must be applied. The stem correction, in degrees Celsius, is given by

$KL(t_o - t_m) = \text{degrees Celsius}$

- where  $K$  = constant, characteristic of the particular kind of glass and temperature (see Table 11.49)
- $L$  = length of exposed thermometer, °C (that is, the length not in contact with vapor or liquid being measured)
- $t_o$  = observed temperature on thermometer
- $t_m$  = mean temperature of exposed column (obtained by placing an auxiliary thermometer alongside with its bulb midpoint)

For thermometers containing organic liquids, it is sufficient to use the approximate value,  $K = 0.001$ . In such thermometers the value of  $K$  is practically independent of the kind of glass.

TABLE 11.64 Values of  $K$  for Stem Correction of Thermometers

| Temperature, °C | Soft glass | Heat-resistant glass |
|-----------------|------------|----------------------|
| 0–150           | 0.000 158  | 0.000 165            |

Gases:

equations of state for 5.170

permeability constants of polymers and  
rubbers 10.66

physical chemistry equations for 5.169

reduction to standard temperature and  
pressure 2.91

solubility in water at various temperatures 5.3

thermal conductivities at various  
temperatures 5.148

Van der Waals' constants 5.157

velocity of 5.171

Gaussian distribution curve 2.119

Geometric mean of set of numbers 2.118 2.119

Geometrical isomerism 1.43

Geometrical isomers, sequences rules for 1.44

Geometry, molecular 4.56

Germanium, bond dissociation energies 4.45

gravimetric factors 11.50

Gibbs energies of formation:

of inorganic compounds 6.81

of organic compounds 6.5

Glycerol-water mixtures:

density and viscosity of 5.138

freezing point of 5.85

Glycine, formation constants with 8.94

Gold, bond dissociation energies 4.45

gravimetric factors 11.50

Graft copolymers 10.3

Graham's law of diffusion, of gases 5.171

Grating equation 7.40

Gravimetric analysis, reagents for 11.67

Gravimetric factors 11.41

Gravitational constant 2.4

Gravity-latitude corrections for barometer 2.75

Greek alphabet 2.25

GRN rubber 10.59

Group dipole moments 4.54

Group refractions 5.136

Gutta percha 10.58

Hafnium, bond dissociation energies 4.45

Haggenmacher equation 6.3

Half-lives, of nuclides 4.59

Half-wave potentials, voltammetric:

of inorganic materials 8.141

of organic materials 8.146

Haloalkanes, Raman frequencies of 7.80

Halogen compounds:

infrared frequencies of 7.62

Raman frequencies of 7.86

Halogen-carbon bond lengths 4.36

Halogen derivatives (organic),

nomenclature of 1.31
